Regent's Park, London NW1 4RY.

SPECIAL DISCOUNT SALE

The following publications are offered as a package at a substantial discount (appx. 25%).

Bell, T. 1843. Herpetology of the "Beagle". (paperbound only) Part V of Darwin's classic "The Zoology of the Voyage of the H.M.S. Beagle". Contains descriptions of 46 species of amphibians and reptiles collected on that renouned expedition. 100 pages, 20 plates, 8½ x 11 in. Introduction by Roberto Donoso-Barros.

Chang, M.L.Y. 1936. Amphibiens urodeles de la Chine. (paperbound only). The standard work on Chinese salamanders with a new checklist by Arden Brame. Illus., 5½ x 8½ in.; 168 pages, 5 plates.

Dunn, E.R. 1926. Salamanders of the Family Plethodontidae. A recognized classic treatment of the plethodontid salamanders, including tropical and European species. A new introduction by David Wake and Arden Brame provides a modern appraisal of this work. Illus., 6 x 9 in.; 472 pages, 3 plates, 86 maps, index.

De La Espada, D.M.J. 1875. Vertebrados del Viaje al Pacificico. A reprint of the most famous of Espada's works in herpetology. An essential reference for anyone interested in the amphibians of South America. With an introduction and biography by J.M. Savage. 208 pages, 6 plates.

Fitzinger, L.J. 1843. Systema Reptilium. An important nomenclatural landmark for herpetology, including amphibia as well as reptiles; world-wide in scope. 6 x 9 in.; 128 pages, portrait. Introduction by Robert Mertens.

Cumulative Index to the Journal of Herpetology, Volumes 1-10.

Package Price: $55.00 Offer valid through 30 June 1983.

The package price includes postage within the United States. Non-U.S. orders include an additional $5.00 for postage. Payments in U.S. funds or international money orders only. Make checks payable to "SSAR". No additional discounts to book dealers. Send orders to:

A REVIEW OF THE DISEASES AND TREATMENTS OF CAPTIVE TURTLES

by

James B. Murphy and Joseph T. Collins

This book is a review of the vast literature on diseases and treatments of captive turtles, with direct reference to approximately 600 citations in the text plus a supplemental bibliography of over 300 titles. Chapters consist of: ***Environmental Factors Affecting Captive Turtles; Bacterial, Viral, Mycotic and Algal Infections of Captive Turtles; Protozoan Infections of Captive Turtles; Helminth Infections and Arthropod Infestations of Captive Turtles; Dietary Deficiencies of Captive Turtles; Non-Infectious Diseases and Injuries of Captive Turtles; Surgical Procedures for Turtles; and Necropsy Techniques and Specimen Collection for Turtles.*** An index to scientific names used in the text is included.

National Museum Act 1983 Grant Programs

The objectives of the National Museum Act are to make possible a continuing study of museum problems and opportunities, both in the United States and abroad; to encourage research in museum philosophy and techniques; and to provide support for training career employees in museum practices.

The grant programs offered under the Act are designed to meet these objectives. As described in the 1983 National Museum Act Guidelines, support is available for research and studies to investigate critical museum problems; professional assistance projects to address shared needs in the museum field; and projects providing opportunities for professional museum training. Throughout all the National Museum Act programs, major attention is given to proposals dealing with museum conservation: the study of conservation problems, research leading to new or improved conservation techniques, and training of museum conservators.

The National Museum Act is administered by the Smithsonian Institution. An Advisory Council consisting of eleven museum professionals assists in establishing the policies governing the grant programs and in evaluating projects for which support is requested.

The National Museum Act Advisory Council will accept grant applications from:

- Museums, including zoos, planetaria, herbaria, and botanical gardens.
- Academic institutions offering courses in museum theory, practice, and skills.
- Nonprofit professional museum-related organizations, institutions, and associations engaged in activities designed to advance museum training, studies, and practices.
- Individuals employed or sponsored by the organizations described above; individuals must apply through an eligible organization.

Funds *cannot* be awarded for:

- The general operating expenses of an organization.
- The expenses of construction, repair, renovation, or restoration of buildings, facilities, or exhibits, or the expenses of planning such work.
- Purchase of collections or equipment.

If you require further information or need assistance in preparing an application, please contact:

SSAR CELEBRATES SILVER ANNIVERSARY

The 25th Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League in Raleigh, North Carolina, during 1-6 August 1982. Under the leadership of Ray E. Ashton, Jr., the conference was hosted by the North Carolina State Museum of Natural History. By every measure, the event was a resounding success and is believed to be the largest herpetological meeting ever held, with an official registration of 530 and an estimated attendance in excess of 600. The meeting took place on the campus of Meredith College in Raleigh, where all sessions were held and most persons were housed and took their meals. This self-contained aspect added to the friendly and productive nature of the meeting.

There were registrants from many countries including Australia, Canada, England, France, India, Italy, Japan, México, the Netherlands, New Zealand, Panamá, Poland, Puerto Rico, South Africa, South Korea, Spain and West Germany, as well as officers from all of the world's major herpetological societies whose presence highlighted the Society's Silver Anniversary. As one measure of the continuing success and drawing power of the Society's joint meetings, two satellite conferences were held at nearby sites immediately before and after the Raleigh meeting: the "Sixth Symposium on Propagation and Husbandry of Captive Reptiles" (Washington, D.C., 29-31 July) and the "Conference on Plethodontid Salamanders" (Highlands Biological Station, North Carolina, 7-10 August).

Letters of greetings on the Society's anniversary were received by SSAR President Kraig Adler from leading herpetologists, societies and other persons. Among them was a congratulatory letter from Ronald Reagan, President of the United States, noting the Society's rapid growth since 1958 and its innovative service to the entire herpetological community. Governor James A. Rhodes of Ohio wrote that "We are proud that the Society had its beginnings in Ohio" and to note the growth of SSAR into the largest society devoted to the scientific study of amphibians and reptiles.

It was a highly successful meeting, both in terms of scientific discussions and in the informal interactions that occurred. Certainly it was a most fitting way to celebrate the Society's first 25 years and set a standard for the future.

THE WHITE HOUSE

WASHINGTON

June 30, 1982

I am delighted to send warmest greetings and congratulations on the 25th anniversary of the Society for the Study of Amphibians and Reptiles.

As members of the largest professional herpetological society, you can take great pride in your organization's record of growth and innovation. In a short time you have grown from a small regional group of amateur herpetologists to an international organization of professionals. Your rapid progress has been the result of increased and imaginative service to the herpetological community in the areas of science, education, and conservation. You have harnessed the energies and talents from the entire herpetological community and, in so doing, have created a society that demonstrates the greatness that can be achieved through a spirit of cooperation and initiative.

Again congratulations at this milestone and my best wishes for every continued success in the years ahead.

Sincerely,

Ronald Reagan

Letter of congratulations from President Ronald Reagan, sent on the occasion of the Society's Silver Anniversary.

SSAR Board of Directors Meeting

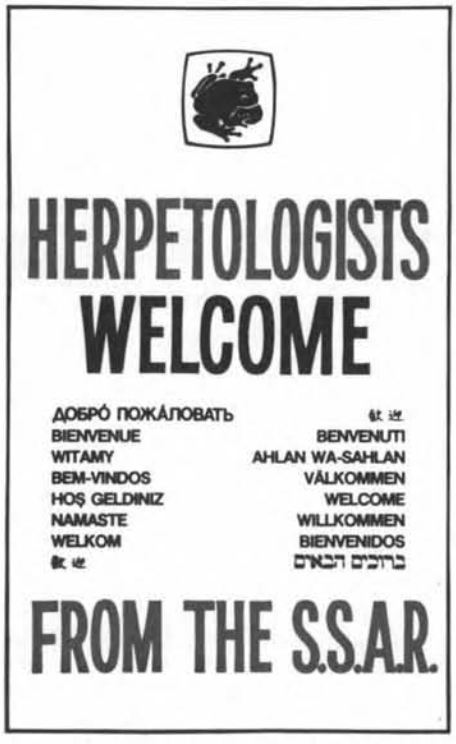
The annual meeting of the Board was held on Sunday, 1 August, under the chairmanship of Kraig Adler. All Board members were present plus other officers, editors, committee chairs and a large number of visitors, most of whom remained throughout the 12-hour meeting to consider a vast range of topics. With six different publication series and an active committee system, there were many important and often highly complex issues to resolve. The main decisions were announced at the Business Meeting on 5 August (see below).

The Board adopted the largest annual budget in the Society's history ($80,000, for 1983). In addition, it reviewed plans to publish Peter C. H. Pritchard's book, the "Turtles of Venezuela," in 1983; this project alone will cost about $90,000. The Treasurer, Henri C. Seibert, announced that Society membership was at its highest level ever for a comparable month of the year and that, by the end of 1982, he confidently expected membership to reach a new record, a tribute to the continuing attractiveness of Society programs and the enormous progress made by the Society in the relatively short span of 25 years.

Opening Ceremonies

At the official start of the meeting, 8:00 AM on 2 August, Ray Ashton, Chairman of the Local Committee, welcomed the group, followed by greetings from Quentin W. Lindsey, Science Advisor to and on behalf of the Governor of North Carolina, and John B. Funderberg, Director of the North Carolina State Museum of Natural History.

The meeting was officially called to order by Kraig Adler who welcomed and individually introduced the many official representatives of national and international herpetological societies, who were asked to stand and be recognized. Because of the special anniversary, Adler then introduced each of the present and past officers and editors of SSAR and its predecessor, The Ohio Herpetological Society, who rose to enthusiastic applause in recognition of their enormous collective efforts over 25 years. To further honor these persons, they were asked to chair the various paper sessions at the meeting.



Following these introductions, Robert F. Inger, President of the Herpetologists' League, added his welcome and introduced the League's Distinguished Speaker, Thomas

M. Uzzell, who presented a special lecture entitled "In Praise of Common Widespread Frogs." Immediately afterward the official group photograph was taken.

International Congress

On a recommendation of the joint SSAR-HL-ASIH Herpetological Resources Committee at last year's Memphis meeting, a temporary committee (David B. Wake (ch.), William E. Duellman and John W. Wright) was established to investigate the feasibility of having a Congress of Herpetology. Comments were solicited by the committee from leading herpetologists around the world and, because of the large international representation at Raleigh, it was decided to convene a dinner meeting, on 2 August, to discuss a Congress. The group included officers and official representatives of all the world's major herpetological societies and other international visitors, all of whom were enthusiastic about establishing an International Congress to be held in four or five years at a site to be decided.

Nominated by Marinus S. Hoogmoed of the Netherlands, Kraig Adler was presented as the sole candidate for Secretary-General, and he was unanimously elected and given the responsibility to establish an international advisory committee. After the committee establishes its plans they will be announced officially via herpetological and other journals.

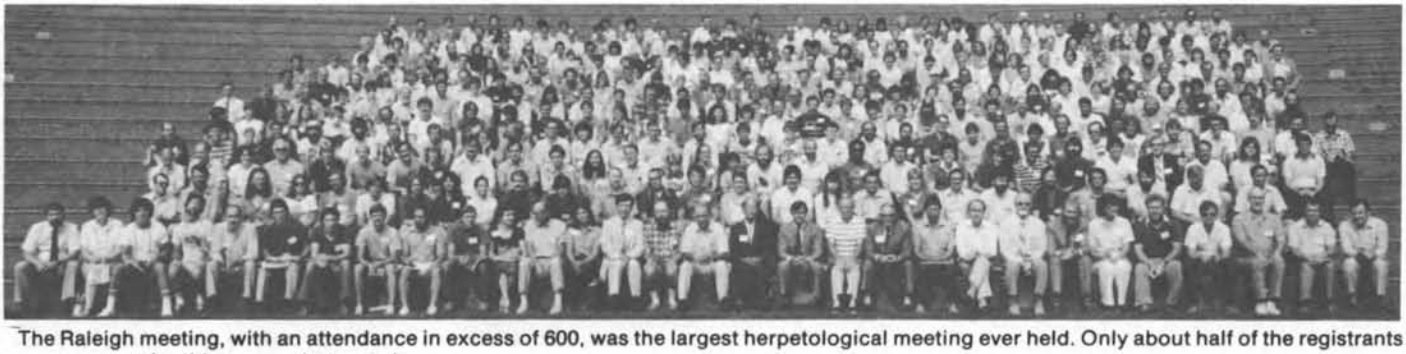
Several multilingual signs were used at the meeting. Registrants represented some 18 different countries from all parts of the world.

Special Symposia, Workshops, and Shows

In addition to the traditional scientific paper presentations, a large number of other events took place at Raleigh, most of them sponsored by SSAR. The highlight of the meeting was an extremely successful two-day symposium arranged and funded by SSAR and organized by David B. Wake entitled "Molecular and Genomic Evolution of Amphibians and Reptiles," consisting of 22 invited papers and an open panel discussion by an international group including the leading specialists in the field. As an adjunct to this symposium, Herbert C. Dessauer arranged informative demonstrations of equipment and techniques illustrating many of the procedures used in gathering the kind of data presented in the symposium. In a special minisymposium organized by Ray E. Ashton, Jr., five well-known researchers presented lengthy talks on controversial aspects of their work, followed by often highly-spirited discussion with the audience. This resurrection of an old idea in paper presentation was highly popular; it was chaired by Herndon G. Dowling.

The Regional Herpetological Societies Conference, now in its 6th year, was sponsored by the SSAR Regional Herpetological Society Liaison Committee, chaired by Janice Perry. This year's program included semi-popular lectures by leading authorities on many topics, all of them richly illustrated with slides and films. The format proved to be highly popular and the two-day event was well attended. Another successful program, sponsored by the SSAR Zoo Liaison Committee chaired by Bern Tryon, was a one-day session entitled "Funding Possibilities for Herpetological Research in Zoos, Museums and Universities". Gary W. Ferguson arranged for representatives from several granting agencies to speak and, later, they held private consultations with interested persons concerning their ideas for research projects.

Two extraordinary multi-media slide shows, simultaneously involving three screens and six projectors, were presented. "Amphibians of the Appalachians," arranged by David M. Dennis and Eric Juterbock, featured a seasonally-changing display of breathtaking photographs of animals and scenery. A second show entitled "Herpetologists Past and Present," produced by David Dennis and Kraig Adler, included a 200-year historical panorama, often highly humorous, of herpetologists and their activities. Both shows attracted standing-room-only crowds and were repeated several times by popular demand. These were followed by an open session where many members brought their own slides to show; this session lasted into the early morning hours!



Several workshops were also held at Raleigh. The IUCN Tortoise Group, chaired by Peter Pritchard, had a public meeting and discussion, followed by a session of the Gopher Tortoise Council arranged by Robert Mount. David Dennis, Eric Juterbock and Ray Ashton ran a photography workshop, a how-to-do-it session that was most popular.

Social Events and Tours

Several social events were organized, allowing for informal discussions. One evening social was held at the State Fairgrounds during which, under the deft hand of auctioneer Joseph T. Collins, nearly $1700 was raised to support the local meeting expenses by selling books and other herpetological paraphernalia including many SSAR publications donated for the purpose. The auction itself was great fun, having become an instant tradition after being started at the Memphis meeting last year. Another evening was spent at the VFW Lodge in Carey which included a pig pickin', the North Carolina version of a barbecue. No one left hungry!

Past and present SSAR officers and editors gathered at a special banquet on 4 August to celebrate the Society's Silver Anniversary. SSAR President and co-founder Kraig Adler reviewed the history of the Society with the assistance of slides provided by David Dennis, the other co-founder. Most of the officers of the old Ohio Herpetological Society also were present for the reunion, to join in for a champagne toast to the Society's future.

A number of tours were sponsored by the Local Committee including the North Carolina State Museum of Natural History, local historic sites, the Governor's mansion, the

The Raleigh meeting, with an attendance in excess of 600, was the largest herpetological meeting ever held. Only about half of the registrants were present for this group photograph.

North Carolina State University Arboretum, textile mills, etc. On the last day of the meeting, 6 August, all-day field trips were taken to the unique Sand Hills of Southeastern North Carolina, arranged by Alvin Braswell, and to the McKaine Tract in the Carolina coastal plain, led by David S. Lee.

Business Meeting

The annual business meeting of SSAR was called to order by President Kraig Adler at 13:30 hr on 5 August. President Adler welcomed SSAR members and visitors.

Treasurer Henri Seibert reported that (1) SSAR's membership will reach a new record by the end of 1982; (2) there has been a deceleration in the rate of growth, however, mostly in student members; (3) Society finances are intact and there will be no increase in dues for 1983; (4) the SSAR Board of Directors approved a budget of $80,000 for 1983; and (5) the Society mailing list is being computerized and any changes of address should be sent immediately to the Treasurer.

Secretary James Jacob asked members to encourage colleagues and students who are not SSAR members to apply for membership. A domestic membership drive is ongoing and its success will be partially dependent upon the support of SSAR members.

Journal of Herpetology Editor Rodolfo Ruibal reported that (1) the *Journal* is receiving some 170 manuscripts per year of which about 45% are accepted; (2) the *Journal* is publishing approximately 70 manuscripts per year, but this may increase with the new printing format employed by Allen Press; and (3) time between *original submission* and publication is less than one year. Ruibal acknowledged the dedicated efforts of the *Journal* reviewers during the past year.

Adler announced a change in the editorship of *Herpetological Review* effective 1 January 1983. George Pisani will resign as Editor and assume the position of Managing Editor. Martin J. Rosenberg will be the new Editor.

Catalogue of American Amphibians and Reptiles Editor Stephen Tilley announced that (1) 25 accounts are being published again this year, with the first group scheduled to appear in the fall of 1982 and the second early in 1983; (2) a *Catalogue* index (thru account 320) will be provided with the second group of 1982 accounts; and (3) all past *Catalogue* accounts, a complete set of tabs, and a 1982 subscription will soon be available for a limited period of time for the special discount price of $95 (details are announced elsewhere in this issue of *Herpetological Review* 13). (see page 114)

Facsimile Reprints Editor Kraig Adler announced that (1) Anderson's "Herpetology of Arabia," with an introduction by Alan Leviton, will appear in 1983, and (2) SSAR will reprint Daudin's "Histoire Naturelle des Rainettes, des Grenouilles et des Crapauds" in 1984, jointly with Société Herpétologique de France, with an introduction by Jean Lescure. As Editor of the *Contributions to Herpetology* series, Adler also announced that Peter Pritchard's "Turtles of Venezuela" will appear in 1983.

President Adler noted that the second edition of "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" has been published in the *Herpetological Circulars* series and is selling rapidly. He announced that SSAR will publish and sell a membership list (dated 31 December 1982) as a *Herpetological Circular* in early 1983. It will also include addresses of all herpetological societies in the world. He also announced that, beginning 1 January 1983, J. T. Collins will move from Editor to Associate Editor and that Neil Ford will assume the Editorship of *Circulars*.

Publications Secretary Douglas Taylor reviewed the activities of his office during 1981, noting that (1) $18,564 was received from about 6,000 transactions, (2) a 10-year index for the *Journal of Herpetology* is now available for purchase, and (3) there will be limited-time special discounts available on SSAR publications in the near future (details are announced in this issue of *Herpetological Review*). (see page 167)

Lynne Houck, Chair of the joint SSAR/HL Meeting Site Committee, announced that (1) John Legler will host the 1983 meeting on the campus of The University of Utah in Salt Lake City during 7-12 August, (2) a site for the 1984 meeting has yet to be chosen [later, it was decided to meet at The University of Oklahoma, jointly with HL and ASIH, 29 July - 4 August 1984], and (3) a meeting in Mexico City is being considered for a later date.

Grants-In-Herpetology Committee Chair Martin J. Rosenberg announced the names of the winners in each category for 1982 and the titles of their proposals (see *HR* 13(3):70). Rosenberg acknowledged the excellent work of his committee. He also announced that the awards for 1983 will be increased to $450 per category.

The report of the Nominating Committee was presented by John Wright, Committee Chair. The nominees for SSAR office in 1983 are:

President-Elect:
James Bacon and Carl Gans
Secretary:
James Jacob (unopposed)
Treasurer:
Henri Seibert (unopposed)
Board of Directors:
John Behler, Hugh Quinn, Linda Maxson, and Larry Wilson

No additional nominations were received from the floor. The ballot for 1983 appeared in the September issue of *Herpetological Review*.

President Adler announced that Christine Maguire was the winner of the 1982 Kennedy Award for the best student paper published in *Journal of Herpetology* in 1981, for her paper entitled *"Plethodon glutinosus* metabolism: applicability to natural populations."

The floor was opened to new business and Paul Hertz made a motion (seconded by Itzchak Gilboa) to adopt the following resolution:

Whereas, an Equal Rights Amendment has been reintroduced in the U.S. Congress and will require ratification by state legislatures for eventual incorporation into the U.S. Constitution and,

Whereas, the ratification of the Equal Rights Amendment is intended to guarantee the equality of professional opportunities and remuneration,

Be It Resolved, that the membership of the SSAR make every effort to schedule annual meetings of the Society in states whose legislatures have ratified the ERA.

Commemorative poster by David M. Dennis which was issued to all meeting registrants. Copies of this full-color drawing of an Arizona Gila Monster *(Heloderma suspectum)* are available for purchase from the SSAR Publications Secretary, Douglas H. Taylor, at a cost of $10 including postage.

Henri Seibert introduced the following amendment to the motion: If the proposed resolution endangers the Society's tax-free status, the resolution becomes null and void. The amendment to the motion was defeated, and the motion to adopt the resolution made by Paul Hertz was approved.

There being no further new business, President Adler yielded the floor to Norman J. Scott, Jr. of the Resolutions Committee for presentation of the following resolutions:

1. *Whereas*, the Society owes the Local Committee a great debt of gratitude for their work and dedication, which have provided us with a well organized, informative, and very enjoyable meeting. *Be It Resolved*, that we extend our thanks to the Local Committee Chairman, Ray Ashton, and Committee members: Jesse Perry, Kaye Cross, Marlene Donabedian, William Palmer, Bill Faircloth, David Lee, Alvin Braswell, John E. Cooper, Alexa Williams, David Dennis, Robert Bader, Wayne Van Devender, Sandy Echternacht, George Barthalmus, Mary Kay Clark, and John Funderburg. We would also like to thank the following people for their assistance: Art Pitzer; C. R. Parkhurst; Dan Hudson; Dan Smith; Paul Kumhyr; David Stephan; Maryruth Reiss; Marie Mason; Eloise Cofer; Marjorie Shaw; Mrs. R. P. Ballard; The Cary V.F.W. Post; Western

Seal engraved by Hajime Fukada, President of Herpetological Society of Japan, to commemorate the Silver Anniversary of SSAR. The Chinese characters read, from right to left, "Dragon Snake Avoid Viciousness" in the *Chuàn* (in Japanese, *Ten*) style of 1000-200 B.C. In ancient times, men who went into the mountains or deep forests carried this seal as a charm to avoid dangerous snakes.

Wake 4-H Club; The N.C. State Museum's Junior Naturalists, Junior Curators, and volunteers; Members of the North Carolina Herpetological Society; The North Carolina Natural History Society; The International Affairs and Conservation Departments of the Women's Club of Raleigh; and North Carolina State University.

2. *Whereas*, the Symposium on Molecular and Genomic Evolution has stimulated timely discussion of techniques and ideas pertinent to evolutionary biology, *Be It Resolved*, that we thank Dave Wake and Herb Dessauer for organizing the symposium and coordinating the demonstrations.
3. *Whereas*, we have also enjoyed several excellent programs, *Be It Resolved*, that we thank Jan Perry, for organizing the Regional Society Conference; Gary Ferguson, for the session on grant possibilities for herpetological research; and David Dennis and Eric Juterbock, for their superb slide shows and photography workshop.
4. *Whereas*, the Society officers who retired last year have proved their devotion to the Society by promoting its aims, *Be It Resolved*, that we thank: Bob Webb, for serving as Immediate Past President; George Pisani, for his work as Editor of *Herpetological Circulars;* Barb Paschke, for her efforts as Associate Editor of *Herpetological Review;* Herb Dessauer and Ed Moll for their service as Directors; J. T. Collins for his service as Secretary of the Society; and the late "Duke" Campbell, for serving as Crocodilian Section Editor of the *Catalogue of American Amphibians and Reptiles*.
5. *Whereas*, the Society has celebrated its 25th Anniversary during this meeting, and
   Whereas, the Society has been sustained during these years by the dedication of many people,
   Be It Resolved, that we express our appreciation by singling out a few of the more prominent contributors, to wit: Henri Seibert, who has served the SSAR since 1962 in various capacities, we hope that he will continue to assist for the next 20 years; Joseph T. Collins, who has also served the Society for 20 years in a record number of positions; Kraig Adler and Dave Dennis, co-founders of the Society; and Doug Taylor, for his long years in the critical job of Publications Secretary.
6. *Whereas*, during our Silver Anniversary meeting we have been honored by the presence of many official delegates and officers of national and international herpetological societies;
   Be It Resolved, that we are delighted to welcome the following: William R. Branch (Herpetological Association of Africa); Gregory A. Mengden (Australian Society of Herpetologists); Michael R. K. Lambert and G. A. D. Haslewood (British Herpetological Society); Marinus S. Hoogmoed (Societas Europaea Herpetologica); Jean-M. Exbrayat (Société Herpétologique de France); Konrad Klemmer (Deutschen Gesellschaft für Herpetologie und Terrarienkunde); Benedetto Lanza (Italian Herpetological Group); Hajime Fukada and Richard C. Goris (Herpetological Society of Japan); James D. Fawcett (New Zealand Herpetological Society); Jorge Luis Piñero (Sociedad para el Estudio de los Quelonios, Puerto Rico); and Marvalee Wake (American Society of Ichthyologists and Herpetologists).

The resolutions were adopted unanimously to enthusiastic applause.

President Adler then introduced Ralph Axtell, who will assume the presidency of SSAR in 1983, and presented him with the richly-decorated Society gavel. There being no further business, President-elect Axtell adjourned the meeting at 14:18 hr.

To celebrate the Society's Silver Anniversary, representatives of all major national and international herpetological societies were present. Pictured, from left: **Row 1,** Mrs. Haslewood, G. A. D. Haslewood and Michael R. K. Lambert (England): Jorge Luis Piñero (Puerto Rico); James D. Fawcett (New Zealand); Marinus S. Hoogmoed (the Netherlands); Hajime Fukada and Richard C. Goris (Japan); **Row 2,** Jacek M. Szymura (Poland); Kraig Adler (SSAR); Marvalee H. Wake (ASIH); David J. Ball (England); Robert F. Inger (HL); Konrad Klemmer and H. S. R. Glaser (West Germany); Benedetto Lanza (Italy); W. R. Branch (South Africa); Mrs. Lanza (Italy). Other official representatives present but not pictured: Jean-Marie Exbrayat (France) and Gregory A. Mengden (Australia). This group, together with other international members, also met to consider the feasibility of an International Congress of Herpetology.

Papers and Posters Presented

About 200 papers were presented during the five-day meeting, in three concurrent sessions. Titles are presented below in order of session. Extra copies of the 117-page Program Booklet, which includes abstracts for most of these papers, are available from the SSAR Publications Secretary, Douglas H. Taylor. These can be supplied at cost, $6 within continental USA, $6.50 overseas (prices *include* book rate surface postage; airmail would be an additional charge).

Sixth Annual Regional Society Workshop

EXOTIC PLACES, EXOTIC HERPS: TRAVELS THROUGHOUT THE WORLD
Cosponsored by SSAR Regional Herpetological Society Liaison Committee and The North Carolina Herpetological Society
Moderator: Janice Perry, Dallas Zoo

A VISIT TO STEPHEN'S ISLAND, HOME OF THE TUATARA, *SPHENODON PUNCTATUS*. Ron Goellner, St. Louis Zoo.

CAPTIVE BREEDING AND THE CURRENT STATUS OF THE HERPETOFAUNA OF THE INDIAN OCEAN. Sean McKeown, Honolulu Zoo, Hawaii.

THE EPIDEMIOLOGY OF GRAM NEGATIVE BACTERIA IN REPTILES (film). Richard Ross, Palo Alto, California.

THE SUCCESSFUL BREEDING OF LIZARDS FROM TEMPERATE REGIONS. B.A.W.A. Langerwerf, The Netherlands.

THE HERPETOFAUNA OF THE ANDES. William E. Duellman, University of Kansas.

AUSTRALIAN CHELID TURTLES. John Legler, University of Utah.

THE LIZARDS OF EUROPE AND THE CAUCASUS. B.A.W.A. Langerwerf, The Netherlands.

CROCODILE FARMS IN THAILAND. Robert Bader and Elliot Jacobson, University of Florida.

GOLIATH FROGS IN FACT AND FICTION—HUNTING THE WORLD'S LARGEST FROG. John Behler, Bronx Zoo.

GRANT POSSIBILITIES FOR HERPETOLOGICAL RESEARCH IN ZOOS, MUSEUMS AND UNIVERSITIES
Sponsored by SSAR Zoo Liaison Committee

OPENING REMARKS: Gary Ferguson, Texas Christian University.
NATIONAL SCIENCE FOUNDATION PROGRAMS. Harold Voris, National Science Foundation.
U.S. DEPARTMENT OF INTERIOR PROGRAMS. C. Kenneth Dodd, Office of Endangered Species.
NEW YORK ZOOLOGICAL SOCIETY GRANTS PROGRAM. John Behler, New York Zoological Park.
SMITHSONIAN PROGRAMS. Dale L. Marcellini, National Zoological Park.
FUNDING IN THE PRIVATE SECTOR. Robert A. Thomas, Louisiana Nature Center.
THE CENTER FOR FIELD RESEARCH (EARTHWATCH). Elizabeth McMahan, University of North Carolina.
BUREAU OF LAND MANAGEMENT PURCHASE ORDERS AND CONTRACTS. Kristin H. Berry, Bureau of Land Management.
PANEL DISCUSSION — RESEARCH OPPORTUNITIES IN ZOOS. Panel Members: Hugh Quinn, Moderator (Houston Zoo), Charles Carpenter (University of Oklahoma), James Bacon (San Diego Zoo), Dale Marcellini (National Zoo), John Behler (New York Zoo), and Elliot Jacobsen (University of Florida).

SSAR 25TH ANNIVERSARY SYMPOSIUM
MOLECULAR AND GENOMIC EVOLUTION OF AMPHIBIANS AND REPTILES
Organized by David B. Wake, University of California at Berkeley

INTRODUCTORY COMMENTS: David B. Wake
Introductory Lecture: **GENETIC INFERENCE FROM ELECTROPHORETIC PHENOTYPES OF PROTEINS, AN INTRODUCTION.** Herbert C. Dessauer, Louisiana State University Medical Center.

Session I: PROBLEMS AT THE LEVEL OF POPULATIONS. Moderated by David B. Wake.
IS THE NEWT METAPOPULATION MODEL GENERAL? Douglas E. Gill, University of Maryland.
GENETIC RECOMBINATION IN ZONES OF SECONDARY INTERGRADATION IN AMPHIBIANS AND REPTILES. David L. Jameson, University of Houston.
THE CLONAL NATURES OF THE *AMBYSTOMA JEFFERSONIANUM* COMPLEX. James P. Bogart, University of Guelph (Ontario, Canada).
HYBRID ZONES IN TOADS, GENUS *BUFO*: PATTERNS AND PREDICTIONS. David M. Green, University of California at Berkeley.

Session II: PROBLEMS IN SPECIATION AND SPECIES INTERACTIONS. Moderated by Herbert C. Dessauer.
GENIC DIFFERENTIATION AND ITS CORRELATES IN THE *DESMOGNATHUS OCHROPHAEUS* AND *FUSCUS* COMPLEXES. Stephen G. Tilley, Smith College.
THE CORRELATION BETWEEN REPRODUCTIVE ISOLATION AND GENETIC DIFFERENTIATION IN EASTERN LARGE *PLETHODON*. Richard Highton, University of Maryland.
NATURAL HYBRIDIZATION BETWEEN *BOMBINA BOMBINA* AND *B. VARIEGATA* (ANURA: DISCOGLOSSIDAE): A COMPARATIVE STUDY OF HYBRID ZONE STRUCTURE IN SOUTHERN POLAND AND WESTERN YUGOSLAVIA. Jacek M. Szymura, Jagellonian University (Krakow, Poland).
HYBRIDIZATION BETWEEN SUBSPECIES OF *ENSATINA*. Kay P. Yanev, University of California at Berkeley.
THE RECOGNITION AND RELATIONSHIPS OF SPECIES IN A HIGHLY PAEDOMORPHIC LINEAGE: A BIOCHEMICAL STUDY OF THE MEXICAN AMBYSTOMATID SALAMANDERS. H. Bradley Shaffer, University of Chicago.
SPECIES WITH EXTREME AMOUNTS OF GENETIC DIFFERENTIATION: THE SPECIES PROBLEM IN *RHYACOTRITION* AND *PSEUDOEURYCEA*. David B. Wake, University of California at Berkeley.

Session III: PHYLOGENETIC INFERENCE. Moderated by W. Ronald Heyer, National Museum of Natural History, Washington.
MOLECULAR PHYLOGENIES: FRAMEWORKS FOR ADDRESSING MAJOR EVOLUTIONARY QUESTIONS. Linda R. Maxson, University of Illinois at Urbana-Champaign.
OPPORTUNITIES AND LIMITATIONS OF MICROCOMPLEMENT FIXATION TECHNIQUES. Thomas Uzzell, Academy of Natural Sciences of Philadelphia.
MOLECULAR GENETICS AND SYSTEMATICS OF THE CROCODILIA. Llewellyn D. Densmore, Louisiana State University Medical Center.
THE NEOTROPICAL COLUBRID SNAKE FAUNA: LINEAGE COMPONENTS AND BIOGEOGRAPHY. John E. Cadle, University of California at Berkeley.
BIOCHEMICAL CHARACTERS AND THE RECONSTRUCTION OF TURTLE PHYLOGENIES: RELATIONSHIPS AMONG BATAGURINE GENERA. J. W. Sites, Brigham Young University.

Session IV: ANALYTICAL AND TECHNICAL ADVANCES. Moderated by John W. Wright, Los Angeles County Museum of Natural History.
PATTERNS OF KARYOTYPIC EVOLUTION IN REPTILES. John W. Bickham, Texas A&M University.
CHROMOSOMES, DNA SEQUENCES AND EVOLUTION IN NEWTS AND SALAMANDERS. Herbert C. Macgregor, University of Leicester (United Kingdom).
MITOCHONDRIAL DNA SEQUENCES ANALYSIS AND REPTILIAN SYSTEMATICS: APPLICATIONS IN THE LIZARD GENUS *CNEMIDOPHORUS*. Wesley M. Brown, University of Michigan.
GENOMIC COMPOSITION OF REPTILES: EVOLUTIONARY PERSPECTIVES. Ettore Olmo, University of Naples (Italy).
THE SIGNIFICANCE OF SEX CHROMOSOMES IN THE EVOLUTION OF SALAMANDER GENOMES. Stanley K. Sessions, University of California at Berkeley.
CHROMOSOME BANDING ANALYSIS IN ELAPID SNAKES AND ITS PHYLOGENETIC IMPLICATIONS. Gregory A. Mengden, Australian National University (Canberra City).

Session V: Open Panel Discussion: RESEARCH OPPORTUNITIES AND PROSPECTS. Moderated by David B. Wake.

Eighty present and past Society officers and editors — about three-fourths of all persons serving over the past 25 years — gathered at Raleigh for a special banquet to celebrate the anniversary. Pictured are those individuals who were active during the early days when the Society was The Ohio Herpetological Society (1958-1966), from left: Kraig Adler, Ray Ashton, Paul Daniel, Stephen Tilley, David Dennis, Barry Valentine, Roger Conant, Corson Hirschfeld, Joseph Collins, Ronald Brandon and Henri Seibert.

TECHNIQUES FOR SYSTEMATICS STUDIES FOCUSED AT THE CHROMOSOMAL AND MOLECULAR LEVELS (part of featured symposium).
Demonstrations organized by
Herbert C. Dessauer, Louisiana State University Medical Center

ELECTROPHORETIC METHODS. Robin Lawson, Louisiana State University; Reed Kaltenbach, University of New Orleans; and Herbert C. Dessauer.

PROTEIN FINGERPRINTING AND IMMUNODIFFUSION METHODS. Llwellyn D. Densmore and Herbert C. Dessauer, Louisiana State University Medical Center.

MICROCOMPLEMENT FIXATION. Stanley K. Sessions, University of California at Berkeley.

TISSUE COLLECTION, PACKAGING, AND STORAGE. All contributors.

Special Paper Session
CONTROVERSIAL IDEAS IN HERPETOLOGY
Moderated by Herndon G. Dowling (former SSAR Editor), New York University

TAXONOMIC RECOGNITION OF BIOCHEMICALLY DIFFERENT POPULATIONS. Richard Highton, University of Maryland.

HOMOLOGUES OF PORTIONS OF THE ADDUCTOR-MANDIBULAR IN SNAKES. Samuel B. McDowell, Rutgers University, Newark.

DO MOLECULES EXHIBIT CLOCKLIKE BEHAVIOR. Linda Maxson, University of Illinois at Urbana-Champaign.

FORM, FUNCTION AND EVOLUTION: A SYSTEMATIC PANACEA? Linda Trueb, University of Kansas.

THE AMPHISBAENIA, AN ORDER OF REPTILES? Carl Gans, University of Michigan. [After repeated interruptions by the audience, the author switched his topic to functional morphology.]

POSTER SESSION
Chairman: Arthur Echternacht, University of Tennessee at Knoxville.

TEMPERATURE RELATIONSHIPS IN *CROTALUS HORRIDUS*. Lauretta M. Bushar, Lehigh University.

EMBRYONIC DEVELOPMENT AND GROWTH WITH *TYPHLONECTES COMPRESSICAUDUS* (APODA: AMPHIBIA). CONSTITUTION OF AN ECTOTROPHOBLAST. J. Delsol, J. Flatin, J.-M. Exbrayat and J. Bons, Laboratoire d'Etude du Développment post-embryonnaire des Vertébrés Inférieurs et Laboratoire de Biogéographie et Ecologie des Vertébrés de l'Ecole Pratique des Haustes Etudes - Laboratoire de Biologie de la Faculte Catholiques des Sciences de Lyon, France.

SEASONAL ANDROGENIC AND TESTICULAR ACTIVITY IN ROUGH GREEN SNAKES. James J. Greenhaw, James S. Jacob, and Michael V. Plummer; Memphis State University (JJG, JSJ) and Harding University (MVP).

LAMPBRUSH CHROMOSOMES AND THEIR DEVELOPMENT IN *PSEUDOBRANCHUS*. James Kezer, University of Oregon.

AN ANALYSIS OF HYBRID ZONE BETWEEN TWO SUBSPECIES OF *ENSATINA ESCHSCHOLTZI*. Robert J. Macey, Berkeley, California.

A USEFUL COLOR GUIDE FOR FIELD STUDIES. Roy W. McDiarmid, Fish and Wildlife Service, National Museum of Natural History, Washington.

INTER- AND INTRASPECIFIC CHANGES IN TURTLE POPULATIONS DURING THE LAST DECADE IN AN OZARK RIVER. Max A. Nickerson and Mark Tohulka, Milwaukee Public Museum and Max Allen's Zoological Gardens.

SYNTHESIS OF INSULIN IN ANOLIAN PANCREAS. William B. Rhoten, University of Medicine and Dentistry of New Jersey - New Jersey Medical School.

ANATOMY OF THE NECK OF THE WESTERN PAINTED TURTLE, *CHRYSEMYS PICTA BELLI*. Tom Scanlon, University of Michigan.

CONTRIBUTED PAPER SESSIONS
Coordinator: R. Wayne VanDevender, Appalachian State University

Session A-1, Chairman: James R. Dixon (former SSAR President), Texas A&M University.

ZOOGEOGRAPHY OF SOUTH AMERICAN TURTLES. Peter C.H. Pritchard, Florida Audubon Society.

GEOGRAPHIC VARIATION IN THE NEOTROPICAL TURTLE, *PLATEMYS PLATYCEPHALA*. Carl H. Ernst, George Mason University.

SYSTEMATICS OF NEOTROPICAL GASTROPOD-EATING SNAKES: THE GENUS *SIBON*, WITH COMMENTS UPON *DIPSAS* AND *SIBYNOMORPHUS*. Christopher P. Kofron, Louisiana State University.

PRELIMINARY COMMENTS ON THE ZOOGEOGRAPHY OF TRINIDAD'S HERPETOFAUNA. John C. Murphy, Plainfield, Illinois.

THE *RANA PIPIENS* COMPLEX IN LOWER CENTRAL AMERICA. David M. Hillis and John S. Frost, University of Kansas.

SPECIATION IN BUFONID GENUS *OREOPHRYNELLA*. Roy W. McDiarmid and S. Blair Hedges, Fish and Wildlife Service, National Museum of Natural History, Washington and University of Maryland.

Poster sessions, arranged by the Herpetologists' League, allowed for an alternative to oral presentation of research results. Authors were present at prescribed times to allow for personal discussions. This productive format will be continued and expanded at future meetings.

LIZARD TAIL AUTOTOMY: FUNCTION AND ENERGETICS OF POST-AUTOTOMY TAIL MOVEMENT. Benjamin E. Dial, Texas A&M University.

Session A-2, Chairman: Harry W. Greene (former SSAR Director), University of California at Berkeley.

SEASONALITY IN TROPICAL LIZARD REPRODUCTION: CONSEQUENCES OF FORAGING MODE? Laurie J. Vitt, Savannah River Ecology Laboratory and University of Georgia.

WHY NEST BURROW PIRACY DOESN'T WORK FOR IGUANAS. A. Stanley Rand, Smithsonian Tropical Research Institute, Panama.

SELECTION FOR A RESTRICTED NESTING SEASON IN THE GREEN IGUANA *(IGUANA IGUANA)*. Brian C. Bock, University of Tennessee at Knoxville.

DIET SELECTION AND DIGESTION IN *IGUANA IGUANA*: THE IMPORTANCE OF AGE AND NUTRIENT REQUIREMENTS. Katherine Troyer, University of California at Davis and Smithsonian Tropical Research Institute.

THE FUNCTION AND UTILIZATION PATTERN OF POSTHATCHING YOLK STORES IN A HERBIVOROUS LIZARD, *IGUANA IGUANA*. Katherine Troyer.

LIFE HISTORIES FOR TWO SPECIES OF *SPHAERODACTYLUS* (GEKKONIDAE) IN PUERTO RICO. Ava Gaa, University of Puerto Rico.

Session A-3, Chairman: Carl Gans (former SSAR Director), University of Michigan.

TAXONOMIC SIGNIFICANCE OF VERTEBRAE FROM RECENT COLUBRID SNAKE GENERA OF NORTH AMERICA (NORTH OF MEXICO). Barbara Brummer, New York University.

ARE THE SCALE COUNTS USED IN SNAKE SYSTEMATICS HERITABLE? Stevan J. Arnold, University of Chicago.

SYSTEMATIC IMPLICATIONS OF ONTOGENETIC CHANGES IN THE CRANIAL MORPHOLOGY OF SNAKES. Randy H. Vaeth, Louisiana State University.

CHARLES CAMP AND THE PHYLOGENETIC RELATIONSHIPS OF THE LIZARD FAMILIES. Scott M. Moody, Ohio University.

MORPHOLOGY AND FUNCTION OF THE TONGUE IN ANT-EATING LIZARDS. Kurt Schwenk, University of California at Berkeley.

THE USE OF THE TONGUE AND HYOID APPARATUS DURING FEEDING IN LIZARDS. Kathleen K. Smith, Duke University Medical Center.

LOCOMOTOR PATTERNS IN SOME CREPUSCULAR SKINKS OF AUSTRALIA. Carl Gans and Allen Greer, University of Michigan and the Australian Museum, Sydney.

Session B-1, Chairman: Barry D. Valentine (former SSAR Vice President), Ohio State University.

DIGITAL LOSS AND REDUCTION IN AMPHIBIANS: AN APPROACH THROUGH ONTOGENY, PHYLOGENY AND EXPERIMENTAL EMBRYOLOGY. Pere Alberch, Harvard University.

TAIL MORPHOLOGY, TAIL INJURIES, AND DEFENSIVE BEHAVIOR IN SAND BOAS, GENUS *ERYX:* A PRELIMINARY REPORT. R.A. Sajdak, D.H. Sorensen, and M.A. Strand; Milwaukee County Zoo and University of Wisconsin-Milwaukee.

THE STATUS OF THE *BILINEATA* GROUP OF WEST INDIAN *LEPTOTYPHLOPS*. Richard Thomas, University of Puerto Rico.

EMPIRICAL APPROACHES TO THREE PROBLEMS IN REPTILE ECOLOGY. Harry W. Greene, University of California at Berkeley.

***ANOLIS SAGREI* AND *A. CRISTATELLUS* IN SOUTHERN FLORIDA: A CASE STUDY IN INTERSPECIFIC COMPETITION.** Mark A. Salzburg, University of Miami.

A COMPARISON OF REPRODUCTIVE CHARACTERISTICS IN PARTHENOGENETIC AND BIPARENTAL SPECIES OF *CNEMIDOPHORUS* (LACERTILIA: TEIIDAE). James M. Walker, University of Arkansas.

RATTLESNAKE ENVENOMATION IN TUCSON, ARIZONA: 1973-1980. David L. Hardy, University of Arizona.

Session B-2, Chairman: James Christiansen (former SSAR Assistant Publications Secretary), Drake University.

OSTEOLOGY AND ONTOGENY OF CANNIBALISTIC LARVAE IN *AMBYSTOMA TIGRINUM*. Dave Darda, University of California at Berkeley.

PHYSIOLOGICAL-ECOLOGY OF THERMOREGULATION IN SNAKES. Andrew F. Dull, Ohio University.

HEART RATE-TEMPERATURE RELATIONSHIP IN JAPANESE RAT SNAKES. Hajime Fukada, Kyoto, Japan.

EVOLUTION OF THERMAL SENSITIVITY OF SPRINT SPEED IN SOME AGAMID LIZARDS. Paul E. Hertz, Raymond B. Huey, and Eviatar Nevo; Barnard College, University of Washington, and University of Haifa, Israel.

CORRELATES OF TEMPERATURE AND BEHAVIOR IN *SCELOPORUS MALACHITICUS*. James L. Vial, University of Tulsa.

MORPHOLOGY AND FUNCTION OF THE FEEDING APPARATUS IN *DERMOPHIS*. Marvalee H. Wake, William E. Bemis, and Kurt Schwenk; University of California at Berkeley.

Session B-3, Chairman: J. P. Kennedy (former SSAR Editor), University of Texas Health Center, Houston.

AMERICAN TOADS AND SWEDISH LUMBERJACKS: A UNIFIED VIEW OF PATTERNS IN EXERCISE PHYSIOLOGY. Theodore L. Taigen and Carol A. Beuchat, University of Connecticut and University of Arizona.

HOW BODY SIZE AFFECTS SWIMMING PERFORMANCE IN THE CLAWED FROG, *XENOPUS LAEVIS*. Kirk Miller, Franklin and Marshall College.

ANAEROBIC METABOLISM IN SWIMMING TADPOLES. R.E. Gatten, Jr., J.P. Caldwell, and M.E. Stockard; University of North Carolina at Greensboro and Savannah River Ecology Laboratory.

ASYMMETRICAL DIFFUSION OF SODIUM AND WATER THROUGH SEA SNAKE SKIN. William A. Dunson and Glenn D. Stokes, Pennsylvania State University.

Live displays, arranged by the North Carolina Herpetological Society, occupied several rooms and included nearly every species of amphibian and reptile from North Carolina and surrounding states. This traditional display, inaugurated at the 1968 SSAR meeting, helps to conserve local fauna by allowing people to remove and photograph captive specimens; many terrestrial and aquatic stages were set up in adjacent rooms for use as photographic backgrounds. In addition, a popular photographic workshop was conducted at Raleigh.

SODIUM LOSS IN AMPHIBIAN LARVAE EXPOSED TO LOW pH. Joseph Freda and William A. Dunson, Pennsylvania State University.

LOCALIZATION OF FOUR HORMONES IN OPHIDIAN PANCREAS. William B. Rhoten, University of Medicine and Dentistry of New Jersey-New Jersey Medical School.

NOSTRIL CLOSING MECHANISMS IN FROGS. Rebecca Pyles and Carl Gans, University of Kansas and University of Michigan.

Session C-1, Chairman: Stephen R. Edwards (former SSAR Secretary and Editor), University of Kansas.

MATING CALLS OF HYBRID TOADS AT LONG POINT, ONTARIO. David M. Green, University of California at Berkeley.

SYNCHRONIZED CALLING AND OTHER PREDATOR DEFENSES OF THE FROG *SMILISCA SILA*. Michael J. Ryan and Merlin D. Tuttle, Cornell University and Milwaukee Public Museum.

MORPHOMETRICS AND HABITAT PARTITIONING OF CLOUD FOREST *ELEUTHERODACTYLUS*. Linda S. Ford, University of Kansas.

NEST DEFENSE BY BROODING MALES OF A SUBTROPICAL FROG. Daniel S. Townsend, State University of New York at Albany.

SYNCHRONIZED RESPONSES TO CONSPECIFIC AND HETEROSPECIFIC CALLS IN THE NEOTROPICAL FROG *HYLA EBRACCATA*. Kentwood D. Wells and Joshua J. Schwartz, The University of Connecticut.

GENETIC RELATIONSHIPS OF THE CHORUS FROGS, GENUS *PSEUDACRIS*. S. Blair Hedges, University of Maryland.

FM SIGNALS AND SPECIES RECOGNITION IN A NEOTROPICAL FROG. Michael J. Ryan, Cornell University and Smithsonian Tropical Research Institute.

Session C-2, Chairman: Joseph T. Collins (former SSAR President, Secretary, and present Editor), University of Kansas.

MAINTENANCE OF POSTMETAMORPHIC RANIDS ON ARTIFICIAL FEED. Joseph K. Buttner and George W. Nace, University of Michigan.

MULTIPLE EGG CLUTCHES IN *HYLA REGILLA, HYLA CINERA* AND *HYLA GRATIOSA*. Stephen A. Perrill and Richard E. Daniel, Butler University and Savannah Science Museum.

A SEASONAL SHIFT IN CHOICE OF EGG-LAYING SITES IN THE SOUTHERN LEOPARD FROG, *RANA UTRICULARIA*. Janalee P. Caldwell, Emory University.

PHYLOGENETIC RELATIONSHIPS OF THE OLD WORLD TREEFROGS — I. INTERFAMILIAL RELATIONSHIPS. Darrel Frost and David Cannatella, University of Kansas.

PHYLOGENETIC RELATIONSHIPS OF THE OLD WORLD TREEFROGS — II. INTRAFAMILIAL RELATIONSHIPS. David Cannatella and Darrel Frost, University of Kansas.

RELATIONSHIPS OF EASTERN NORTH AMERICAN RANID FROGS. Barbara Pytel, New York University.

REPRODUCTIVE PARTITIONING AND SPECIES DIVERSITY: AN HYPOTHESIS BASED ON STUDIES OF LEOPARD FROGS. John S. Frost, University of Kansas.

Session C-3, Chairman: Douglas H. Taylor (present SSAR Publications Secretary), Miami University.

BEHAVIORAL AND PHYSIOLOGICAL CORRELATES OF FORAGING MODE IN LACERTIDS. Raymond B. Huey, Albert F. Bennett, Henry John-Adler, and Kenneth A. Nagy; University of Washington, University of California at Irvine, University of California at Los Angeles.

ACTIVITIES AND MOVEMENTS OF THE WESTERN SLENDER GLASS LIZARD, *OPHISAURUS ATTENUATUS ATTENUATUS*. David M. Morton, Miami University.

A COMPARISON OF THE MOVEMENTS OF EASTERN BOX TURTLES, *TERRAPENE C. CAROLINA, ON AND AWAY FROM THEIR HOME RANGES*. Stephen Porter Hall, University of North Carolina at Chapel Hill.

SHORELINE MOVEMENT IN A NONBREEDING POPULATION OF *RANA CATESBEIANA*. M.L. Manis, Miami University.

VISUAL CUES: FEEDING RESPONSE OF *HYLA CINEREA* TO NATURAL PREY. Arthur N. Freed, University of Florida.

SURVIVAL OF EMBRYOS AND LARVAE OF THE FROG, *POLYPEDATES LEUCOMYSTAX* IN MALAYSIA. Callyn D. Yorke, University of Arkansas.

RED, WHITE AND BROWN: PRELIMINARY OBSERVATIONS ON THE COLOR OF CENTROLENID TADPOLES (AMPHIBIA: ANURA: CENTROLENIDAE). Jaime Villa and Carlos

Valerio, University of Missouri-Kansas City and University of Costa Rica, San Jose.

Session C-4, Chairman: Henri C. Seibert (former SSAR Director and Publications Secretary, present Treasurer), Ohio University.

CONSPECIFIC SUBSTRATE PREFERENCES IN THREE SYMPATRIC WATER SNAKES, *NERODIA CYCLOPION CYCLOPION, NERODIA FASCIATA CONFLUENS,* AND *NERODIA RHOMBIFERA RHOMBIFERA.* Barbara Allen, Daniel S. York, and Gordon M. Burghardt, University of Tennessee at Knoxville.

COMPARATIVE STUDY OF DEFENSIVE BEHAVIOR IN THREE SPECIES OF *NERODIA.* Roy M. Scudder and Gordon M. Burghardt, University of Tennessee.

ALTERNATIVE MATING STRATEGIES IN AMPHIBIANS. T.R. Halliday and P.A. Verrell, The Open University (England).

PREDATORY BEHAVIOR OF THE RED SPITTING COBRA *(NAJA MOSSAMBICA PALLIDA).* Charles W. Radcliffe, Karen Estep, and David Chiszar, University of Colorado.

AN ANALYSIS OF FEEDING BEHAVIOR IN A BICEPHALIC BLACK RAT SNAKE. Gordon M. Burghardt, Bruce G. Batts, and Brian C. Bock, University of Tennessee at Knoxville.

SPECIES DENSITIES OF SNAKES AND THEIR POTENTIAL PREY: A RE-EVALUATION. Kenneth Miyata, National Museum of Natural History, Washington.

Session D-1, George Pisani (present SSAR Editor), University of Kansas.

SEASONAL TIMING OF MATING, SPERM STORAGE AND MULTIPLE PATERNITY IN SINGLE LITTERS IN THE COPPERHEAD, *AGKISTRODON CONTORTRIX.* Gordon W. Schuett and James C. Gillingham, Central Michigan University.

FIELD STUDY OF POPULATIONS OF THE TIMBER RATTLESNAKE, *CROTALUS HORRIDUS.* William S. Brown, Skidmore College.

ECOLOGY OF PRAIRIE RATTLESNAKE, *CROTALUS VIRIDIS,* AT THE NORTHERN LIMIT OF ITS RANGE. V.P.G. Gannon and D.M. Secoy, University of Regina (Canada).

GEOGRAPHIC VARIATION IN REPRODUCTIVE CYCLES AND STRATEGIES OF *THAMNOPHIS MARCIANUS.* John P. Karges, University of Texas at Arlington.

THE REPRODUCTIVE CYCLE OF THE SOUTHEASTERN CROWNED SNAKE. R.D. Aldridge and R.D. Semlitsch, St. Louis University and Savannah River Ecology Laboratory.

COMPARATIVE ECOLOGY OF THE RACER, *COLUBER CONSTRICTOR.* Philip C. Rosen, Wayne State University.

ECOLOGY OF A POPULATION OF PLAINS GARTER SNAKES *(THAMNOPHIS RADIX)* IN SOUTHERN SASKATCHEWAN. Marie Selinger, University of Regina (Canada).

Session D-2, Chairman: James L. Vial (former SSAR President and Director), University of Tulsa.

PATTERNS OF RELATIVE CLUTCH MASS IN SNAKES. Richard A. Seigel, University of Kansas.

COTTONMOUTH ACTIVITY PATTERNS IN NORTHWEST FLORIDA. David G. Cook, University of Florida and Tall Timbers Research Station.

DIFFERENTIAL HABITAT UTILIZATION BY SYMPATRIC *CROTALUS HORRIDUS* AND *AGKISTRODON CONTORTRIX:* A MULTIVARIATE APPROACH. Howard K. Reinert, Lehigh University.

GEOGRAPHICAL VARIATION IN THE SEX PHEROMONE DISCRIMINATION ABILITY OF THE PLAINS GARTER SNAKE, *THAMNOPHIS RADIX.* Neil B. Ford, University of Texas at Tyler.

CRYPSIS AND FITNESS IN A SNAKE INTERGRADE COMPLEX. Samuel S. Sweet, University of California at Santa Barbara.

Session D-3, Chairman: Paul M Daniel (former SSAR Vice President), Miami University.

MT. ST. HELENS: THE SURVIVING HERPETOFAUNA. James A. MacMahon, Utah State University.

AMPHIBIANS AND REPTILES OF THE SOMALI DEMOCRATIC REPUBLIC. Benedetto Lanza, University of Florence (Italy).

HOLOCENE EXTINCTION OF A HERPETOFAUNA FROM ANTIGUA, BRITISH WEST INDIES. Gregory K. Pregill, San Diego Natural History Museum.

RECENT STUDIES OF THE LADDS HERPETOFAUNA, LATE PLEISTOCENE, NORTHWESTERN GEORGIA. J. Alan Holman, Michigan State University.

A MOST REGRETABLE TANGLE OF NAMES REVISITED: THE THOMPSON-VAN DENBURGH FEUD IN THE EARLY 20th CENTURY. Alan E. Leviton and Michele L. Aldrich, California Academy of Sciences and American Association for the Advancement of Science.

VARIABILITY IN RATE OF MITOCHONDRIAL DNA EVOLUTION IN AMPHIBIANS. Christina Spolsky, Academy of Natural Sciences of Philadelphia.

MITOCHONDRIAL DNA ORIGINS IN AN INTERSPECIFIC *RANA* HYBRID. Christina Spolsky and Thomas Uzzell, Academy of Natural Sciences of Philadelphia.

Session D-4, Chairman: Thomas Fritts (present SSAR Director), U.S. Fish and Wildlife Service.

EFFECTS OF TEMPERATURE AND SALINITY ON GROWTH RATES OF HATCHING CROCODILES AND ALLIGATORS: IMPLICATIONS FOR THEIR DISTRIBUTION IN SOUTHERN FLORIDA. Frank J. Mazzotti, Pennsylvania State University.

GROWTH RATES OF AMERICAN ALLIGATORS IN NORTH CAROLINA. M.K. Fuller, P.C. Smithson, S.E. Klause, and P.D. Doerr; North Carolina State University.

THE ORINOCO CROCODILE IN SOUTHERN VENEZUELA. Richard Franz, Florida State Museum.

A BIO-TELEMETRY STUDY OF THE BEHAVIOR AND THERMAL BIOLOGY OF THE AMERICAN ALLIGATOR. Larry D. Vangilder, Richard T. Hoppe, and Robert A Kennamer; Savannah River Ecology Laboratory.

THE RANGE AND DISTRIBUTION OF THE AMERICAN ALLIGATOR IN NORTH CAROLINA. P.C. Smithson, P.D. Doerr, and O.T. Sanders; North Carolina State University.

HOMOLOGIES OF THE DORSAL ARMOR OF CROCODILIANS. Gregory C. Mayer and Franklin D. Ross, Harvard University.

COURTSHIP, MATING AND COMBAT IN THE TUATARA, *SPHENODON PUNCTATUS.* J.C. Gillingham, C. Gans, and D. Clark; Central Michigan University and University of Michigan.

Session E-1, Chairman: Max A. Nickerson (former SSAR President, Editor and present Director), Milwaukee Public Museum.

SEASONAL REPRODUCTIVE CHANGES IN *CRYPTOBRANCHUS ALLEGANIENSIS.* Chris A. Ingersol and Robert F. Wilkinson, Southwest Missouri State University.

REPRODUCTION, GROWTH, AND MATURITY OF *PLETHODON WEBSTERI* IN SOUTH CAROLINA. Raymond D. Semlitsch and Carolyn A. West, Savannah River Ecology Laboratory and University of South Carolina at Sumter.

THE EFFECTS OF TEMPORAL ISOLATION AND THE DURATION OF BROODING ON CLUTCH RECOGNITION BEHAVIOR BY THE MOUNTAIN DUSKY SALAMANDER. Don C. Forester and Keith Harrison, Towson State University.

REPRODUCTIVE EFFORT IN THE SALAMANDER *DESMOGNATHUS FUSCUS:* A PRELIMINARY REPORT. J. Eric Juterbock, Ohio State University, Lima Campus.

AGGRESSION IN THE SALAMANDER *DESMOGNATHUS MONTICOLA.* W. Hubert Keen and Steven Sharp, State University of New York College at Cortland and University of Tennessee.

THE ENERGETIC COST OF COURTSHIP AND AGGRESSION IN THE PLETHODONTID SALAMANDER *DESMOGNATHUS OCHROPHAEUS.* Albert F. Bennett and Lynne D. Houck, University of California at Irvine and University of Chicago.

THE CLOACAE OF MALE DESMOGNATHINAE. David M. Sever, Saint Mary's College.

Session E-2, Chairman: Ronald A. Brandon (former SSAR President and Director), Southern Illinois University at Carbondale.

PARALLELISM, CONVERGENCE AND NOVELTY IS THE RULE IN LIMB EVOLUTION IN *THORIUS.* James Hanken, Dalhousie University (Canada).

PATTERNS OF INNERVATION IN THE TONGUE OF PLETHODONTID SALAMANDERS. Gerhard Roth, D.B. Wake, and M.H. Wake, University of Bremen (West Germany) and University of California at Berkeley.

SALAMANDERS OF THE GENUS *BOLITOGLOSSA* FROM OAXACA AND GUERRERO. Theodore J. Papenfuss, David B. Wake, and Kraig Adler; University of California at Berkeley and Cornell University.

THE ECOLOGY OF BEHAVIORAL THERMOREGULATION IN NEOTROPICAL SALAMANDERS. Martin E. Feder, University of Chicago.

OLFACTORY COMMUNICATION OF THE SALAMANDER *PLETHODON GLUTINOSUS.* Ellen M. Dawley, University of Connecticut.

FURTHER OBSERVATIONS ON THE TAXONOMIC STATUS OF TWO COLOR PATTERN MORPHS OF *EURYCEA QUADRIDIGITATA* (HOLBROOK) IN NORTH AND

SOUTH CAROLINA. Julian R. Harrison, The College of Charleston.

THE *AMBYSTOMA* SALAMANDER OF LAGUNA ALCHICHICA, PUEBLA, MEXICO. Ronald A. Brandon, Edward J. Maruska, and William T. Rumph; Southern Illinois University at Carbondale, Zoological Society of Cincinnati, and Staten Island, N.Y.

Session E-3, Chairman: Robert E. Gordon (former SSAR President), University of Notre Dame.

LARVAL BIOLOGY OF *EURYCEA* IN THE SOUTHERN APPALACHIANS. Richard C. Bruce, Highlands Biological Station and Western Carolina University.

GROWTH OF LARVAL RED SALAMANDERS, *PSEUDOTRITON RUBER*, IN NORTHWESTERN NORTH CAROLINA. Robert Wayne VanDevender, Appalachian State University.

THE INTERACTION BETWEEN LARVAE OF *AMBYSTOMA OPACUM* AND *AMBYSTOMA MACULATUM*. Christopher R. Chambers, Duke University.

CHROMOSOME EVOLUTION IN SALAMANDERS OF THE GENUS *NECTURUS*. Stanley K. Sessions and John E. Wiley, University of California at Berkeley and St. Paul's College, Virginia.

CHROMOSOME VARIATION IN THE DWARF SIREN *PSEUDOBRANCHUS STRIATUS*. James Kezer, University of Oregon.

POSSIBLE ORIGIN OF A POPULATION OF *HYLA VERSICOLOR*. J.E. Wiley, St. Paul's College, Virginia.

PROTEIN DIVERGENCE OF *NECTURUS BEYERI* AND *N. PUNCTATUS*. Reed M. Kaltenbach, University of New Orleans.

Session E-4, Chairman: Diane M. Secoy (former SSAR Assistant Publications Secretary), University of Regina, Saskatchewan, Canada.

FURTHER STUDIES OF TEMPERATURE DEPENDENT SEX DETERMINATION IN *CHELYDRA SERPENTINA*. E.C. Houghtaling and D.C. Wilhoft, Rutgers University, Newark.

EGG SIZE IN TURTLES: CONSTRAINT ON OPTIMAL EGG SIZE. Justin D. Congdon and J. Whitfield Gibbons, Savannah River Ecology Laboratory.

OVERWINTERING OF HATCHLING *CHRYSEMYS PICTA*. Gary L. Breitenbach, University of Michigan.

EMBRYONIC DIAPAUSE IN TURTLE EGGS. Michael A. Ewert, Indiana University.

SYSTEMATICS OF *LEPIDOPHYMA* POPULATIONS IN THE SIERRA MADRE ORIENTAL OF MEXICO. Robert L. Bezy, Natural History Museum of Los Angeles County.

ENVIRONMENTAL FACTORS OF ONSHORE FEMALE *CHELYDRA SERPENTINA* ACTIVITY. D.C. Wilhoft and E.C. Houghtaling, Rutgers University, Newark.

NEST-SITE SELECTION, NESTING BEHAVIOR, AND HATCHLING EMERGENCE IN THE SOUTHERN BLACK-KNOBBED SAWBACK, *GRAPTEMYS NIGRINODA*. Pete N. Lahanas, Auburn University.

Session F-1, Chairwoman: Margaret M. Stewart (former SSAR President), State University of New York at Albany.

NESTING OF THE GREEN TURTLE, *CHEONIA MYDAS*, IN FLORIDA. C.K. Dodd, Jr., U.S. Fish and Wildlife Service.

LIFE HISTORY ASPECTS OF *CHRYSEMYS PICTA* AND *STERNOTHERUS ODORATUS* POPULATIONS IN VIRGINIA. Joseph C. Mitchell, University of Richmond.

REPRODUCTIVE VARIATION BETWEEN TWO POPULATIONS OF *STERNOTHERUS ODORATUS* IN THE SAME GEOGRAPHIC AREA. R. McPherson and K.R. Marion, Clarion State College and University of Alabama in Birmingham.

EFFECTS OF PHOTOPERIOD AND TEMPERATURE ON REPRODUCTIVE CYCLE AND BEHAVIOR OF *STERNOTHERUS ODORATUS*. Mary T. Mendonca, University of California at Berkeley.

THE STRIPED MUD TURTLE *KINOSTERNON BAURI* IN SOUTH CAROLINA: A CONFIRMATION THROUGH MULTIVARIATE CHARACTER ANALYSIS. Trip Lamb, Savannah River Ecology Laboratory.

REPRODUCTIVE ECOLOGY AND POPULATION STRUCTURE OF THREE TROPICAL TURTLE COMMUNITIES. Richard C. Vogt, Instituto de Biología, UNAM (Mexico).

Session F-2, Chairman: Sherman A. Minton (former SSAR Director), Indiana University School of Medicine.

SOME FACTORS INFLUENCING THE DISTRIBUTION OF *TESTUDO GRAECA* L. (TESTUDINES, TESTUDINIDAE) IN MOROCCO PRECLUDING ITS SURVIVAL IN COLD, TEMPERATE EUROPE. M.R.K. Lambert, British Herpetological Society, London.

THE CONGENER-INDUCED DISPLACEMENT OF COLOR PATTERN FEATURES IN FOUR KENTUCKY HERPTILES, WITH EVIDENCE FOR THE SPECIFICITY OF *LAMPROPELTIS ELAPSOIDES*. John R. MacGregor, Kentucky Department of Fish and Wildlife Resources.

A PROPOSED ORIGIN OF NESTING LOCATION DIVERGENCE AND A SHARED FEEDING RANGE IN BRAZILIAN GREEN TURTLE POPULATIONS. Don Moll, Southwest Missouri State University.

BODY TEMPERATURES, MOVEMENT AND DIVING CYCLES OF A JUVENILE LEATHERBACK TURTLE, *DERMOCHELYS CORIACEA*. E.A. Standora, J.R. Spotila, J.A. Keinath, and R.C. Shoop; State University College at Buffalo and University of Rhode Island.

ASPECTS OF LARVAL TOAD ECOLOGY. Thomas J. Berger, University of Kansas.

THE MALE REPRODUCTIVE CYCLE OF THE QUEEN SNAKE, *REGINA SEPTEMVITTATA* IN WESTERN PENNSYLVANIA. J.J. Minesky and R.D. Aldridge, St. Louis University.

REPRODUCTIVE CYCLE IN *TYPHLONECTES*. J.-M. Exbrayat, Laboratoire de Biologie de la Faculte Catholique des Sciences de Lyon, France.

Session G-1, Chairman: George Zug (former SSAR Director and Editor), National Museum of Natural History, Washington.

KINGSNAKE SYSTEMATICS: STATUS OF *LAMPROPELTIS GETULUS GOINI*. D. Bruce Means, Tall Timbers Research Station, Florida.

ANURAN SEX-LINKED GENES BEHAVE DIFFERENTLY THAN MAMMALIAN ONES. Richard P. Elinson, University of Toronto (Canada).

Herpetological art and craft displays and commercial exhibits and sales have become a major and popular attraction at Society meetings. Pictured are a display of color photographs by Society members and the work of Thomas McFarland (seated), an artist who specializes in hand-painted ceramic turtles. Other sales included T-shirts, books, carvings, scientific equipment and other herpetological materials.

BIOCHEMICAL SYSTEMATICS OF THE THAMNOPHIINI: THE GENERA *NERODIA* AND *REGINA*. Robin Lawson, Louisiana State University.

AN ELECTROPHORETIC ANALYSIS OF SOME GERRHONOTINE LIZARDS. David A. Good and John W. Wright, University of California at Berkeley and Los Angeles County Museum of Natural History.

GENETIC ISOLATION OF TWO SUBSPECIES OF *ANOLIS DISTICHUS*? S.M. Case and E.E. Williams, Salem State College and Harvard University.

GENETIC VARIATION IN MAINLAND *ANOLIS CAROLINENSIS*. J.K. Wade, A.C. Echternacht, and G. McCracken; Pennsylvania State University and University of Tennessee at Knoxville.

GEOGRAPHIC VARIATION IN CRICKET FROGS. Wendy Gorman, University of Kansas.

Session G-2, Chairman: C.J. McCoy (former SSAR President), Carnegie Museum of Natural History.

AN EMBRYONIC STUDY OF FIVE SPECIES OF *ANOLIS* USING GROWTH CURVES AS A BASIS FOR STAGING. Lisa Levinson, New York University.

GENETIC VARIATION IN THE COTTONMOUTH WATER MOCCASIN *AGKISTRODON PISCIVORUS* AT THE NORTHERN EDGE OF ITS DISTRIBUTION. Donald A. Merkle, Longwood College.

CHANGES IN THE DISTRIBUTION OF *CROTALUS HORRIDUS*. W.H. Martin, Harper's Ferry, West Virginia.

MORPHOMETRICS OF HIGH-ANDEAN *ATELOPUS* IN ECUADOR, SOUTHERN COLOMBIA, AND NORTHERN PERU. Peter Gray, University of Kansas.

DIGITIZED HERPETOLOGY. Itzchak Gilboa, City University of New York.

THE COMBAT RITUAL OF THE MALAYSIAN PIT VIPER *(CALLOSELASMA RHODOSTOMA)*. Daniel S. York, University of Tennessee at Knoxville.

CHROMOSOME MORPHOLOGY OF AFRICAN SNAKES. W.R. Branch, Port Elizabeth Museum (South Africa).

Committees for 1982-1983.

Following the Raleigh meeting, President Adler appointed the following committees, coordinators and representatives for the current year, to report to the Board at the Salt Lake City Meeting in August of 1983. Individuals with important matters pertaining to these activities should contact the relevant committee chair. Addresses for committee chairs are included on the inside rear cover of each issue of **Herpetological Review.**

Grants-in-Herpetology: Linda Maxson (ch.), Donald Forester, Dale L. Marcellini, Robert Mount, Malvin Skaroff.

Conservation (formerly Herpetological Habitats Committee and incorporating Legislative Alert Committee): John Behler (ch.), James P. Bacon, C. Kenneth Dodd, René Honegger, Paul E. Moler, Patricia Riexinger, Laurie J. Vitt.

Kennedy Student Award: Gary Ferguson (ch.), W.R. Branch, Janalee Caldwell, Eric Juterbock, Murray J. Littlejohn, P.E. Vanzolini, Ernest E. Williams.

Nominating: James Vial (ch.), Theodore L. Taigen, Diane Secoy, Douglas H. Taylor, John W. Wright.

Regional Society Liaison: Janice Perry (ch.), Robert Bader, Jeffrey Black, James Harding, William Holmstrom, Michael R.K. Lambert, Joseph Mitchell.

Zoo Liaison: John D. Groves (ch.), Hans Boos, Julian Duval, W.-E. Englemann, Gary Ferguson, Ronald Goellner, William Holmstrom, Hans-Günter Petzold, Bern Tryon.

Long-range Planning: James Jacob (ch.), Kraig Adler, James Christiansen, Carl Gans, Samuel McDowell, James Murphy, Henri Seibert, Margaret Stewart.

Meetings (SSAR/HL) (formerly Meeting Site Committee and incorporating Symposium Coordinator): Lynne Houck (ch.), Ray Ashton, Jr., Michael Seidel, James Jacob, Ronald Brandon.

Local Meeting (Salt Lake City): John Legler (ch.), others to be appointed by Legler.

Resolutions (SSAR/HL): Daniel Wilhoft (ch.), others to be appointed at Salt Lake City meeting.

Herpetological Resources (SSAR/HL/ASIH): Roy McDiarmid (ch.), Pere Alberch, Alan Leviton, Scott Moody, Charles Myers, Linda Trueb.

Translations Coordinator: Robert Aldridge.

Special Meeting Topics Coordinator: Ray Ashton, Jr.

Representative to Association of Systematic Collections: C.J. McCoy.

JAMES S. JACOB
SSAR Secretary ●

SSAR TRANSLATIONS PROJECT

The object of this project is to make available to SSAR members accurate translations of foreign language research articles. Since SSAR has not budgeted money for translation of articles, we must rely on contributions from members. If you have an article that has been translated, please send a copy (or reprint) of the original and the translation to the editor. A few people have volunteered to translate articles and we are interested in hearing from any others who are willing to contribute their time.

If you have an article for translation that you feel would appeal to a large segment of the herpetological community, send a copy or reprint to the editor and we will try to have it translated.

Since the first list of translations was published (Herp. Review 10(3): 82-83, 1979) we have added 16 new titles (marked SSAR). Copies of these are available (.05/page) through the Translation's Project Editor, Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, MO 63103.

In addition a list of articles available through the National Museum of Natural History is included (marked SHIS). Copies of these are free and may be obtained by writing SHIS, Division of Reptiles and Amphibians, National Museum of Natural History, Washington, DC 20560.

Beuchelt, Hans. 1936. Bau, Funktion und Entwicklung der Begattungsorgane der Mannlichen Ringelnatter (*Natrix natrix* L.) und Kreuzotter (*Vipera berus* L.). Part 6. Erection of the Penes. Morph. Jahrb. 78:445-516 **(avail. SSAR).**

GOPHER TORTOISE COUNCIL ANNUAL STUDENT AWARD

The GTC offers a cash award to a student pursuing an undergraduate or graduate degree who is planning or actively conducting research involving the gopher tortoise, *Gopherus polyphemus*. The 1982 award was $400.00. The only obligations of the recipient, other than conducting the proposed research, are to submit to the GTC a copy of their final report within 6 months of the project completion date, acknowledgement of the GTC in appropriate scientific papers, and copies of any papers that originate from the research. Proposals should be short, no more than 3 double-spaced typed pages, and should include a brief biographical section, a description and justification of the research, and a budget indicating how the money will be spent. Further information is available from: Dr. Dale R. Jackson, Florida Natural Areas Inventory, 254 E. Sixth Avenue, Tallahassee, FL 32303.

NEW *HR* EDITOR

With a certain and definite regret, I decided late last year to resign as **HR** editor effective with this issue. It's been fun, challenging, educational and a chance to serve a society I truly enjoy. But there are now many more demands upon my time than ever before, and SSAR is blessed with abundant talented members to fill its roles. As each editor perhaps does, I've developed a very personal feeling about **HR** and its readership, and have attempted to structure each issue to serve as broad a cross section of that readership as possible. I'm confident that **HR** will continue to move ahead under the new editor (Martin J. Rosenberg, Dept. of Biology, Case Western Reserve University, Cleveland, OH 44106). Please direct all manuscripts, advertising and correspondence about **HR** to Marty. I've agreed to serve as Managing Editor through 1983, and thereafter hope to serve SSAR in some other capacity.

The very first thing an editor learns is that a hell of a lot of dedicated help is needed to produce a publication, especially one as diverse as **HR.** Hence, my sincere thanks to all of the Section Editors for their considerable investment of time and energy the past six years, and also to Barb Paschke, who invested so much effort developing **HR's** advertising program and helping in numerous other ways. The Biology Department here at KU is certainly to be commended for providing a host of oft unsung support facilities. Thanks also to the various officers and board members for their support of **HR,** and to our printer, Steve Meseraull, and his staff for making the job vastly easier and being patient with my faux pas. Sincerest thanks to you, the readership, for your written and vocal support, as well as your support via submission of excellent material — it's tough to publish a quality product if no one sends any articles !! Hopefully, some plans on the not too distant horizon will reduce our abominable lag time in publishing feature articles. Finally, but by no means least, my very special thanks to Joseph T. Collins for his invaluable assistance and guidance as co-editor for three years and his unswerving support and advice all along.

Cheers!
GRP ●

FUTURE ANNUAL MEETINGS

1983 The University of Utah, Salt Lake City, Utah, 7-12 August (John M. Legler, Chairman).

1984 University of Oklahoma, Norman, Oklahoma, 29 July - 4 August (Victor H. Hutchison, Chairman). ●

HR REVIEWERS

We gratefully acknowledge the help of the following persons who reviewed manuscripts.

Miguel Alvarez del Toro
Ralph Axtell
J. Kevin Bowler
Charles C. Carpenter
William Coil
Daler Khan
Robert Henderson
Hobart M. Smith ●

SSAR ACKNOWLEDGES COMMITTEE SERVICE

In addition to its many publications series, SSAR also serves the herpetological community through its active committee system. During the past year nearly 80 persons served on committees and the Society would like to acknowledge their important service. Although space prevents us from noting each person here we would like to thank them all by listing the following retiring committee chairs and representatives for 1982:

Martin J. Rosenberg (Chair, Grants-in-Herpetology Comm.)
James Gillingham (Chair, Kennedy Student Award Comm.)
Hugh Quinn (Chair, Legislative Alert Comm.)
John W. Wright (Chair, Nominating Comm.)
Bern Tryon (Chair, Zoo Liaison Comm.)
Gordon Burghardt (Chair, Symposium Comm.)
Frances Irish (Chair, Resolutions Comm.)
Alan Leviton (Chair, Herpetological Resources Comm.)
Max A. Nickerson (Representative to the Association of Systematics Collections)

Current committee chairs are listed on the inside rear cover of this issue. ●

LEGISLATIVE ALERT

PROTECTION OF THE SPANISH HERPETOFAUNA

Royal Decree 3181/1980 of 30 December 1980, published in the *Boletín Oficial del Estado* 6 March 1981, protects all but ten amphibian and reptile species (B.O. del E., Núm. 56).

Hunting, capturing, trafficking in, or exportation of any protected species without a permit is now punishable under Spanish law. Permits for collection may be granted if requests are accompanied by a detailed statement of purpose from the applicant's institution. Applications for permits may be sent, in letter form, to:

El Subdirector General
Instituto Nacional para la Conservación de la Naturaleza
Gran Via de San Francisco, 35
Madrid 5, Spain

Permission to export collected specimens is **not** implicit in collection permits and, presumably, must also be granted by the above agency. Anyone wishing to work in Spain would be well-advised to obtain all necessary permits well in advance of anticipated arrival date.

STEPHEN D. BUSACK

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1983 Grants-In-Herpetology Program. This Program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. Grant proposals will be considered in the following areas:

1) **GRADUATE STUDENT HERPETOLOGICAL RESEARCH.** Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.

2) **HERPETOLOGY-ORIENTED CONSERVATION.** Proposals should address research on endangered or threatened species at the state, national or international levels, or address research or critical herpetological habitats. Proposals may be received from individuals only.

3) **REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS.** Proposals may address any herpetological research endeavor or projects, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individual members of the society. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.

4) **HERPETOLOGICAL RESEARCH IN ZOOS.** Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.

Each proposal should include the following information: A) **Background & Objectives** of the proposed project, in terms of its relevance to herpetology, B) **Methods** of carrying out the research or conducting the project, C) **Budget for the project**, which should not exceed $400 in each category, and D) **Curriculum Vitae** and **Letter of Support** (if applicable). The proposal must be typed double spaced and must **not** exceed 5 pages, excluding cover page, abstract, budget, curriculum vitae, and bibliography.

Successful applicants will be expected to submit to SSAR a written report of their research or project, within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to **The Journal of Herpetology** or **Herpetological Review.**

Members of the SSAR Grants-In-Herpetology Committee will evaluate all proposals, projects or programs. Committee members are: Linda R. Maxson (Chairperson), Robert Mount (Conservation Research), Malvin L. Skaroff (Regional Herpetological Society Projects), Donald C. Forester (Graduate Student Research), and Dale L. Marcellini (Zoo Research).

Individuals submitting proposals must designate to which of the four areas their proposals applies. All proposals must be typewritten and submitted in duplicate no later than **15 APRIL 1983** to:

Dr. Linda Maxson
Department of Genetics
and Development
University of Illinois
515 Morrill Hall
505 South Goodwin Avenue
Urbana, Illinois 61801

SPECIAL INTRODUCTORY SUBSCRIPTION OFFER

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The Society for the Study of Amphibians and Reptiles is extending, for a limited period, a special offer to new subscribers to the *Catalogue of American Amphibians and Reptiles*. Individuals who subscribe before *30 June 1983* may purchase their one-year subscription (25 accounts), a complete set of accounts (numbers 1-320), two imprinted post binders, and a set of index tabs for $95. For individuals this represents a savings of $24.50. Institutions who subscribe before *30 June 1983* may obtain the same offering for $139.50 (a savings of $36.00). This includes postage within the U.S.A. — overseas orders must be assessed an additional charge of $5.00.

The *Catalogue of American Amphibians and Reptiles* is a series of loose-leaf accounts treating species and higher taxa of New World amphibians and reptiles. Each account is prepared by an expert on that taxon and occupies 2-4 pages (8½ x 11 inches). It provides a wealth of information, including common and scientific names (with a synonymy), a definition and description, information on fossil occurrence, a detailed map of geographic distribution, and a comprehensive introduction to the literature.

The *Catalogue* is an essential reference for all biologists who use amphibians or reptiles in their research. The loose-leaf format allows individual additions and updating, and provides the option of arranging the accounts in serial, alphabetic, geographic, or taxonomic order.

Individuals wishing to take advantage of this special offer should fill out the form below and send it to:

Dr. Douglas H. Taylor
Publications Secretary,
Society for the Study of Amphibians and Reptiles
Department of Zoology
Miami University
Oxford, Ohio 45056, U.S.A.

Checks should be made out to "Cat. Amer. Amphib. Rept." or "SSAR".
Payment must be in U.S. funds; receipt on request only.

IN MEMORIAM

RICHARD (DICK) M. JOHNSON
1924-1982

On April 28, 1982, our dear friend and comrade was overcome by the ravages of lung cancer that he had been valiantly and courageously battling for eight months. Dick has left behind his wife, Lyn, two daughters, Lt. Commander Judith M. Johnson and Beth P. Young, and a host of friends.

Richard Johnson, as his friend Gordon Moulton wrote, "was an individual concerned about man and his ultimate destiny. He would slight his accomplishments while praising others — one who openly shared his warm love and personality with his family and friends. He lived close to God's earth and its many creatures and has found true contentment within himself. He was a man of integrity, high ideals, sensitivity, compassion and love. As a disarmingly learned man, he became a successful scientist, educator, administrator, father and husband."

We first became acquainted with Dick when he came to Tulane University to pursue an M.S. degree in herpetology under Fred R. Cagle in 1950. It was there that our bonds of friendship were secured and even though our paths took us separate ways in the intervening years we had kept in touch.

One of us, Liner, had for years made collecting trips into Mexico to study the herpetofauna there. In 1970, while attending the ASIH meetings in New Orleans, Dick decided that he would participate in one of these expeditions. He was so impressed after that first trip that he made each annual one thereafter and several additional ones to Yucatan with his wife. When the other member of the trio (Chaney) joined them in 1972, a close working relationship and a three musketeers (margariteers) arrangement was established. We were "mothered" by Dick; he planned the menus, supervised the purchases, cooked most of the meals and fastidiously cleaned the utensils after each meal.

In addition to the menial chores, he was "the finder of the unusual," usually a snake and most often a rattlesnake of some kind. He never seemed to tire, spurred on by his need to see, need to know and need to experience. Not only was he active during the day, but was "up and at 'em" before breakfast, and after the last dish had been cleaned at night. He provided us with expertise in many areas, recreation through musical tapes, relaxation, humor through practical jokes, and most of all love and affection.

Dick was born in Carey, Ohio on March 4, 1924, and spent his formative years there. He served in the Army during WWII in the Philippines, Okinawa and Japan. He returned to college after the war and received his B.S. degree in 1950 from Ohio State University, majoring in Wildlife Management. He received his M.S. from Tulane University in 1952 and Ph.D. from the University of Florida in 1958. He spent two summers at National Science Foundation summer institutes, Duke University in Marine Biology and The University of North Carolina at Chapel Hill in Botany. He became Professor of Biology and Head of Biology Departments at Asheville-Biltmore College, West Georgia College, and Wesleyan College. Recently, until his retirement in 1975, he was Professor and Associate Dean of the College of Arts and Sciences at the University of South Alabama. Since his retirement he had been self-employed with his wife as artistic potters, except for the academic year 1979-1980, when he was asked to assume the deanship of the Coordinate College for Health Professions at the University of South Alabama.

Dick was a member of Sigma Xi, Gamma Sigma Delta, and Phi Sigma honor societies, as well as Beta Theta Pi, a social fraternity. He belonged to the following professional societies: American Association of University Professors, Ecological Society of America, American Institute of Biological Sciences, American Society of Ichthyologists and Herpetologists, Herpetologists' League, and Society for the Study of Amphibians and Reptiles. He is listed in *American Men of Science, Who's Who in South* and *Southwest*, and *Who's Who in American Education*.

Dick was a long-time student of the herpetofauna of the southeastern United States, but in later years extended these interests to northern Mexico. As a result, he had received various grants and had published some 23 papers concerning the herpetofauna of these regions.

His premature death is a blow to us and an irreparable loss to the herpetological community. So adios Amigo until we meet again in the hereafter, rolling rocks, tearing open logs or rubber-banding lizards. Vaya con Dios.

BULLFROG ELIMINATING LEOPARD FROGS IN COLORADO?

The bullfrog *(Rana catesbeiana)* apparently is not a native member of the Colorado herpetofauna. Ellis and Henderson (1913, 1915) knew of no native bullfrog populations in Colorado and stated that introductions of bullfrogs into several ponds and reservoirs in the upper South Platte River valley during the early 1900s were not very successful. In 1943, Rodeck reported that bullfrogs were then known only from Kit Carson County. Swenson and Rodeck (1948) added Denver and the Cimarron River to the areas known to be inhabited by bullfrogs. Maslin (1950) stated that the bullfrog was well established in the vicinity of Wray in Yuma County, in the Cimarron River drainage, and in the Arkansas River valley as far west as Pueblo. In addition to previously known sites, Maslin (1959) recorded bullfrogs from near Fort Morgan, Morgan Co., and from the vicinity of Two Buttes Reservoir, Baca Co. Since 1959 the number of areas known to be inhabited by bullfrogs has increased greatly. Smith *et al.* (1965) listed 12 new county records for bullfrogs in Colorado. Hammerson (1982) mapped all areas known to be occupied by bullfrogs, reporting them in 24 counties. No special study has been made of the bullfrog in Colorado, and the distribution of the species in the state is incompletely known. However, it is clear that the range of the bullfrog has expanded greatly in recent decades and continues to do so.

The presence and range expansion of the bullfrog in Colorado undoubtedly are a result of artificial introductions and the creation of naturally rare, favorable habitat. Prior to human settlement, permanent lakes and ponds were practically nonexistent in lowland areas of Colorado. Today there are hundreds of them, created in response to agricultural, domestic, and recreational water needs, and for flood control. These bodies of water were rapidly colonized by native leopard frogs *(Rana blairi, R. pipiens)* which probably inhabited stream pools and seasonally flooded areas along streams in the lowland areas of Colorado. In 1915, Ellis and Henderson reported that leopard frogs were "very abundant near all of the ponds and lakes in eastern Colorado." The mechanism by which bullfrogs have become widely established in these habitats is somewhat enigmatic. The Colorado Division of Wildlife does not actively introduce or propagate bullfrogs (J. Bennett, pers. comm.). It is possible that bullfrogs are unintentionally introduced during the Division's fish stocking operations; bullfrogs sometimes invade fish hatchery ponds and perhaps bullfrogs occasionally are present among the fishes routinely stocked in Colorado's ponds and reservoirs. Bullfrog larvae can survive among predatory game fishes, which are averse to eating them (Kruse and Francis 1977). I suspect that bullfrogs sometimes are introduced by private citizens hoping to establish a local "huntable" population or to hear their calls on warm summer nights, but I have no information on the extent of such activity. Once a bullfrog population becomes established in an area, frogs may quickly colonize adjacent bodies of water; in southeastern Colorado I have found bullfrogs in recently rain-filled, temporary stock ponds more than a mile (1.6 km) from the nearest permanent water.

Concurrent with the establishment and range expansion of the bullfrog in Colorado has been the decline of the leopard frogs. A few examples will illustrate this obvious but poorly documented trend. Specimens in the University of Colorado Museum indicate that *R. blairi* was relatively abundant and that the bullfrog was present in the area of Sand and Gallinas canyons in Baca County in the late 1940s. A few specimens of *R. blairi* were obtained there in the early 1960s. I visited the same area several times from 1978 to 1982 and all of the approximately 100 metamorphosed frogs and numerous larvae that I observed were bullfrogs; *R. blairi* apparently has been extirpated. Museum records indicate that ponds and pools along the South Platte River in the vicinity of Denver were inhabited by *R. pipiens* in the late 1800s. Today the bullfrog is abundant along the

Platte, but few (if any) leopard frogs remain. At the Sawhill Ponds Wildlife Preserve in eastern Boulder County, 96% of the 93 ranid frogs (not including larvae or newly metamorphosed frogs) that I observed during 1978 and 1979 were *R. pipiens;* only 4% were bullfrogs. In contrast, only 26% of 117 ranid frogs observed from 1980 to 1982 were *R. pipiens;* 74% were bullfrogs. In 1978 I observed bullfrogs in only one of the 12 ponds that I regularly surveyed at the Sawhill Preserve; bullfrogs occupied all of the 12 ponds in 1982. During the last few spring breeding seasons leopard frog egg masses have become increasingly difficult to find. Of the newly metamorphosed ranids observed in 1982 at Sawhill Ponds, bullfrogs outnumbered leopard frogs by at least 20 to 1. Other biologists also have noted the decline of the leopard frog and the increase in the bullfrog population in Colorado (D. Pettus, pers. comm.). I know of 24 areas in Colorado where leopard frogs at least formerly occurred and where bullfrogs are now known to occur. Leopard frogs apparently have been extirpated from several of these areas and currently coexist with (but generally are outnumbered by) bullfrogs in several other areas. Leopard frog status in many of the areas is unknown.

Bullfrogs have been implicated as the cause of the decline of certain native ranid frogs in western North America. Dumas (1966) noted that the spread and increase of the introduced bullfrog in the Pacific Northwest was concurrent with a large decline in the *Rana pretiosa* population. Moyle (1973) felt that the bullfrog was "probably the single most important factor" in the elimination of *Rana aurora* from most of the San Joaquin Valley of California. Presumably the large bullfrog eliminates smaller native ranids through intense predation and competition (Moyle 1973). Inhibitory effects of bullfrog larvae on larval leopard frogs (Rose 1960, Licht 1967) possibly are important. The observations presented here do not conclusively demonstrate that the bullfrog is responsible for the decline of the leopard frog in Colorado. Water pollution, introduced game fishes, and other habitat changes may differentially affect the frogs and account for all or part of the apparent population trends. Moreover, leopard frog populations are declining in areas where bullfrogs are absent (D. Pettus, pers. comm.). The extent and possible causes of the decline of the leopard frog in Colorado have not been adequately studied. However, evidence implicating the introduced bullfrog as the major cause of the decline in native leopard frog populations in at least some areas of Colorado is strong enough to warrant an in-depth study of this possibility. At the very least, systematic monitoring of bullfrog and leopard frog populations at selected localities would be prudent. The Colorado Division of Wildlife, responsible for the management and conservation of both game (bullfrog) and nongame (leopard frog) wildlife, is the logical agency to conduct or support such a study. Hopefully, a leopard frog recovery plan can be formulated and implemented before leopard frogs disappear as important components of lowland ecosystems in Colorado.

I thank Hobart M. Smith for his valuable comments on the manuscript.

LEECH *(PLACOBDELLA PARASITICA)* INFESTATIONS ON THE WOOD TURTLE, *CLEMMYS INSCULPTA*

The presence of leeches on turtles is a common occurrence in nature and is well documented in the literature (see Ernst and Barbour, 1972 for a review). Until recently however, the occurrence of leeches on the Wood Turtle *(Clemmys insculpta)* was poorly documented. Holbrook (1842) and Babcock (1919) mentioned the occurrence of *Clepsina scabra* (= *Placobdella parasitica*) on *Clemmys insculpta* and Ernst and Barbour (1972) also reported the presence of *P. parasitica* on *C. insculpta,* but none of the above authors gave any details. More recently Koffler *et al.* (1978) reported on the seasonal occurrence of *P. parasitica* on *C. insculpta* from New York and New Jersey. Their's was the first paper to discuss in detail the association between leeches and wood turtles. The present paper documents a high level of leech infestation on a population of *C. insculpta* from western Pennsylvania.

Field work was conducted in early April and mid-October of 1978 at Yellow Creek State Park, Indiana County, Pennsylvania. *Clemmys insculpta* were collected adjacent to, but never in, a small woodland stream that enters the southwestern portion of Yellow Creek Reservoir. The stream is slow flowing with a sandy to muddy bottom. Five adult turtles were collected in April and three adult turtles were collected in October. All individuals from both samples were parasitized by *P. parasitica.* Infestations appeared to be heaviest in the October sample, with a total of 8 adults and 142 young leeches on the three turtles. The five turtles from April had a total of seven adults and 153 young. Adults were found on both the shell and exposed soft parts of the body, whereas the young were always found on the soft body parts. Although leeches were found on all exposed areas of the skin (*e.g.* head, neck, legs, arms) certain areas appeared to be preferred. Among these were the inguinal cavity and the nuchal area of the neck and adjacent axillary cavity. These areas are the most inaccessible to the external environment and would afford the leeches the greatest possible protection from desiccation and abrasion while the turtles engaged in terrestrial activity.

Sawyer (1972) stated that adult *P. parasitica* leave the host animal to become free living during mating and incubation. He further stated that the majority of animals remain free living while brooding the young, although an occasional parent may be found brooding on the host. One turtle from the October sample had a brooding individual attached to the left hind leg. The parent had 28 young attached to the ventral surface of its body. Koffler *et al.* (1978) also found brooding individuals on the host. The brooding young were similar in size to the other young found in both the April and October samples. The distribution of the young leeches on the turtles suggests that *P. parasitica* may frequently brood on this population of wood turtles. Of the 267 young leeches found on the turtles, 211 were in eight groups that varied from 14 to 29 individuals per group. All groups were tightly packed, with virtually no space between individuals. The number and positioning of the young in these groups is similar to what one would expect to find in brooding leeches. It is highly probable that these groups represent individual broods deposited by the parents. Koffler *et al.* also noted that the young leeches formed tightly packed masses.

The April sample of turtles had recently emerged from hibernation and the October sample was preparing to enter hibernation. It may be that brooding individuals attach to the turtles in the fall and that they and their young spend the winter dormancy with the host animal, thus assuring a continuous supply of food over the winter. This would account for the heavy infestations on the turtles so early in the season. *Clemmys insculpta* were not

collected between May and September, so we do not know if the leeches remain with the turtles during the summer. Koffler *et al.* noted a marked decline in leech infestations during the summer.

VARANUS "MONITOR": AN INVALID NAME FOR *VARANUS BENGALENSIS*

Prior to the monograph and checklist on the family by Mertens (1942, 1963), the specific name *"monitor"* had been used by various authors for both *Varanus bengalensis* and *V. Salvator* to a lesser extent, for the African *V. niloticus*. Since 1935 when Smith referred *bengalensis* to *monitor*, most of the subsequent confusion involves that single species. The misuse of *monitor* is still used in the literature (Banerjee and Banerjee 1969; Dutt 1968; Jacob and Ramoswami 1976; Sabnis and Rangnekar 1967; and others) causes consternation not only for zoologists, but for agents charged with protecting the endangered species, *V. bengalensis*, as well. *V. monitor* is not a valid specific name (Mertens, 1957) and should not be used.

Proper use of the name *bengalensis* is important because that species is currently listed on Appendix I of the CITIES treaty, legally limiting the exploitation of the lizards, especially on the commercial level. Because many dealers illegally obtain the animals by listing them as *V. "monitor"*, the effect of this use is to negate the protection accorded the species.

At the time that the varanids in this paper were described, the source material for that description was often an illustration from a book about newly explored regions of the globe. The names *Lacerta monitor*, *L. Dracaena* (Linnaeus 1758 and 1766, respectively) and *Stellio salvaquardia* (Laurenti 1768) were all given to a composite specimen illustrated in Seba's (1734) Thesaurus; the illustrated specimen was later identified as *V. salvator* (Laurenti 1768) by Mertens (1957), Thus, *monitor* becomes the oldest available name for *salvator*, while *dracaena* would be a junior synonym.

Daudin (1802) used the combination *Tupinambis bengalensis* fourteen pages after introducing the name *T. cepedianus*, leading Deraniyagala (1953) to propose that the latter name be retained instead of the former. However, Article 24(a) of the International Code of Zoological Nomenclature provides that synonyms for a single taxon appearing in a single work are not given priority by page precedence, and that the final determination of the official name is decided by the first revisor. In this case, the first revisors were Dumeril and Bibron (1936), who retained *bengalensis*.

The name *monitor* became attached to *bengalensis*, in error, by Flower (1929) and has subsequently been used in that sense by some later authors. As both *bengalensis* and *cepedianus* properly apply to this species, and *monitor* does not, the threat to *bengalensis* was not nomenclatural, but a matter of actual usage.

Laurenti (1768) introduced the combination *Stellio salvator*, identifiable in part as *Lacerta monitor* of Linnaeus (and in part as both *bengalensis* and *niloticus*). The name *salvator* was, however, widely used in the literature and became a more stable name for that species.

In order to protect and recognize the most stable names for these varanids, Opinion 540 of the International Commission on Zoological Nomenclature (1957) suppressed the names *dracaena, salvaquardia,* and *monitor.* Since then, most references to *Varanus "monitor"* pertain to *bengalensis*, the authors are apparently unaware of this nomenclatural action or are mislead by animal dealer invoices.

The status of *V. bengalensis* as an endangered species requires its correct identification by law enforcement officials. Most price lists from Asian reptile dealers list the "Bengal Monitor", but use the specific names *"monitor", cepedianus,* or *nebulosus.* As a result of Opinion 540, there are, and cannot be, any varanids with the specific names *monitor* or *cepedianus.* The species *bengalensis* does, however, contain a subspecies *nebulosus,* which could conceivably be elevated to specific names rank; as a subspecies of an endangered species, it too is protected.

Occasionally a dealer will list **any** Varanus with the specific catch-all *"monitor"* — often a clue that the animal was obtained illegally. Since there is no such species, those responsible for examining animal imports should be alert if *"V. monitor"* occurs on the document.

I wish to express my gratitude to Walter Auffenberg and Joseph T. Collins for their comments and help. I particularly want to thank Dr. Hobart Smith for his numerous comments and suggestions on the manuscript from start to finish.

THE ORIGIN OF THE NAME "CANTIL" FOR *Agkistrodon bilineatus*

The widely used vernacular names of copperhead and cottonmouth, for *Agkistrodon contortrix* and *A. piscivorus*, respectively, are readily explained. Copperheads have copper-colored or reddish heads and many cottonmouths, when first encountered in the field, hold their mouths open so the whitish interior can be seen. On the contrary, a satisfactory explanation of the name "cantil" for *A. bilineatus* has eluded us, even though it has long been used by herpetologists in the United States and Middle America, as well as by residents of parts of the latter region.

The Spanish word *cantil* means a steep rock, cliff, or precipice, translations that are difficult to associate with the snake. In response to an inquiry that I addressed to a number of colleagues and correspondents, a variety of suggestions were received. Common among them was the thought that perhaps the name was bestowed because *bilineatus* usually is found in rocky habitats near cliffs, but that supposition is contraindicated by the notes and writings of many persons who have encountered the snake in the field. The idea was also expressed that perhaps the type specimen came from a cliff, but Günther (1863) described the species simply as from the "Pacific coast of Guatemala" and mentioned neither habitat nor common name. Another suggestion was that the strongly developed canthus rostralis is shaped like a cliff, an ingenious thought but a far-fetched one.

The statements of several authors (Sumichrast, 1880; Günther, 1895; and Martín del Campo, 1937) that the name *cantil* was used in Tehuantepec offered a clue, but confirmation of what I had long suspected, that the origin of the word was associated in some way with a native language in a region inhabited by *bilineatus*, was not obtained until recently.

The solution to the problem was discovered by Dr. Miguel Alvarez del Toro, the distinguished naturalist and director of the Instituto de Historia Natural, Departamento de Zoología, in Tuxtla Gutiérrez, Chiapas, and who is the principal authority on the vertebrates of his native state. He wrote, "In a new vocabulary of indigenous languages of Chiapas (Corzo Espinosa, 1980), I found the Tzeltal word "kantiil" was given to this snake. It means yellow lips, from "kan" = yellow and "tiil" = lips. So you see it is very well applied. Such a word was very easily changed to the Spanish *cantil*. The Tzeltals are an indigenous people of Chiapas, and it is certain they have long had communication with the people of Tehuantepec and other adjacent areas."

The wide usage of *cantil* for *Agkistrodon bilineatus* by herpetologists is probably traceable to the popular writings of Raymond L. Ditmars, who employed the name for the species in the many printings of his "Reptiles of the World" (first published in 1910) and "Snakes of the World" (first published in 1931). It is highly likely that Ditmars found the word in Günther's profusely and beautifully illustrated "Biologia Centrali-Americana: Reptilia and Batrachia," the publication of which was completed in 1902, just at the time when Ditmars' career as an author was beginning to flower.

I am grateful to the late Howard K. Gloyd for encouraging me to pursue the subject of this note, and to Hobart M. Smith for suggesting I publish it now instead of waiting until the completion of the long Gloyd-Conant monograph on the genus *Agkistrodon*.

NATURE PRINTS
BY DAVID M. DENNIS

We are pleased to offer exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife. First set of 4 now available: Green frog, Painted turtle, Spotted salamanders, Beetle and Red salamander. Prints measure 20 × 24 inches, each signed and numbered by Mr. Dennis in editions limited to only 500. $25 each or $85 set of 4, plus shipping ($4.50) and any NY taxes. Send orders to Biographics, 12 Eagle's Head Rd., Ithaca, NY 14850. Illustrated brochure on request.

Societas Europaea Herpetologica

Amphibia-Reptilia

The SEH was founded in 1979 by herpetologists from 8 European countries to encourage closer collaboration between European and Non-European scientists. Its publication AMPHIBIA — REPTILIA is a multidisciplinary journal devoted to all aspects of herpetology, to further the interchange of knowledge and ideas between specialists on different subjects, ranging from the use of biochemical technics in herpetological research to electron microscopy, from amphibian and reptilian genetics to the fossil history of the modern amphibians and reptiles, including systematics and taxonomy as well as behaviour, physiology and ecology.
AMPHIBIA — REPTILIA publishes high-quality original papers, short articles on new methods and ideas in progress, book reviews and news of the SEH.

"With current exchange rates for the West German Mark, membership in SEH costs approximately $31."

INSTITUTIONS

DEPARTMENT OF ICHTHYOLOGY AND HERPETOLOGY ROYAL ONTARIO MUSEUM

A phased expansion-renovation project closed the public areas of the Royal Ontario Museum on January 11, 1981. Parts of these areas including the Reptile Gallery are scheduled to reopen in September 1982. This gallery is an interim exhibit derived from the older *Gallery of World Reptiles*, but is now moved to another floor and remounted in new cases with new labels and backgrounds. Within the financial, time, and manpower budgets available, and using very few additional specimens, an effort was made to convey new story lines, and to include more about the identification of local reptiles. Some features of the old gallery, like the American Alligator diorama, were used unchanged.

Planning of the totally new permanent Ichthyology Gallery and Herpetology Gallery, to be opened in the late 1980's, will begin soon. The Herpetology Gallery will place equal emphasis on reptiles and amphibians, the first extensive and "permanent" exhibit of amphibians to be mounted at ROM.

Both of these new and ambitious galleries will result from totally new conceptual designs and story lines.

We ask that readers keep our need for display material in mind. It would be very helpful if we could be made aware of possibilities to acquire specimens of species now difficult to procure. Knowledge of the location of reference specimens posed naturally before fixing and suitable for moulding, or moulds used for models in existing galleries which could be borrowed, would also be most useful.

This department — staff, equipment, collections and all — moved back to ROM in August 1981 after four years in off-site quarters. We now occupy one-half of one of the three underground floors of a nine storey building referred to as the Curatorial Centre. The Curatorial Centre will house all of the collections and labs, and the offices of most curatorial departments.

The old wings (built 1913 and 1933) are being completely renovated and the space occupied in the past by offices, collections, and labs will be used as additional exhibit space. Filling this space with good exhibits will be a challenging task.

BOREAL AMPHIBIAN BIOLOGY

AMPHIBIANS OF CANADA by Barbara Froom, 1982. McClelland and Stewart Limited, Toronto. 120 pp. paperback. $14.95 Canadian.

In 1975 T. Burton and G. Likens reported a most pleasing herpetological discovery. They had found that the resident biomass of salamanders in the hardwood forest of their Hubbard Brook study site equalled the resident mammalian biomass and was about twice that of birds during their yearly peak. Here, at last, was proof that amphibians are an important component of a north temperate ecosystem. The climate and biota at Hubbard Brook, New Hampshire, is very similar to that of large portions of Quebec and the eastern Canadian Maritime provinces, suggesting that amphibians are a major part of the vertebrate biomass in Canada as well as in northern New England. The early spring salamander slicks that cover highways in many parts of southern Canada subjectively reinforces that idea that much of Canada is bountiful in amphibians. Indeed, a quarter of the fresh water on this planet is in Canada and much of that water is in the kettleholes, ponds, pools and puddles left by retreating glaciers — an ideal amphibian habitat.

Admittedly, when one thinks of countries rich in amphibians Canada is not likely the first one that comes to mind. Certainly more tropical countries have higher species diversity. Yet parts of Canada are not doing too badly, at least compared to other northern industrialized countries. There are, for example, six species of *Rana* that can be collected in less than an hour's drive of downtown Halifax despite 280,000 metropolitan area residents.

Amphibians in Canada receive disproportionately little formal study by biologists, certainly less than their biomass, or even their diversity, would warrant. Range boundaries for several of the more cosmopolitan Canadian species are unknown and honest herpetologists (*e.g.*, Conant, 1975) draw range maps for those species with dashed lines separated by question marks every two to four hundred miles.

It is really not surprising that Canadian amphibians have received so little attention. Naturalists in Canada are more readily drawn into the study of either fish or mammals because of their greater economic importance. Herpetologists who like field work traditionally head for the tropics whenever they can. There are signs, however, that the situation is changing and that herpetology, particular amphibian biology, is beginning to develop in Canada. Whereas, for example, there was only one herpetologist from Nova Scotia identified in the 1974 *HISS Yearbook of Herpetology*, now there are at least four biologists in that province with primary research interests in amphibians and who publish on those organisms.

As governments in tropical countries look more and more like road side pools in Kansas in August — overheated, overgrown, and very ephemeral — field oriented herpetologists are likely to look for more politically stable hunting grounds. Canada is a place where one can still make contributions to herpetology by just getting out there and looking.

If, as most evolutionary biologists believe, major evolutionary events take place in peripheral populations then Canada should be a great place to study evolution in progress. After all, most species that extend into Canada meet the limits of their distribution there. Triploid *Ambystoma* populations are relatively common in eastern Canada and the more we learn about their strange genetics (Bogart, 1982) the more one feels that they are witnessing a dynamic evolutionary process.

The most species rich parts of Canada are the coastal regions. These are also the regions with the greatest insularity and peninsularity. Genetic isolation among populations of Canadian amphibians may be substantial given this geography. Considering the number of cryptic species of amphibians that have been discovered in recent decades in southern North America, there may still be amphibian species to be discovered in Canada.

The recent study by Schmid (1982) on freezing in anurans opens up a whole area of study on the cold tolerance of amphibians. What are the limits of cold tolerance for different species, and for those same species from different parts of their range? What is the relationship between temperature, time (rate of freezing, rate of thawing) and survivorship for different species? Does cold tolerance change with development? How does cold tolerance affect species' ranges?

Against this background of much herpetology to do and too few people to do it, one looks enthusiastically to books with titles like *Amphibians of Canada* to identify key problems and inspire investigation. A book with this title has, in fact, just been published by McClelland and Stewart Limited, Toronto. Regrettably the book is far more popular pulp than propaedeutic boreal herpetology. The author, Barbara Froom, is an amateur herpetologist and a long time activist in the Canadian Amphibian and Reptile Conservation Society, CARCS (pronounced "carcass" by more than one of its members). From the book's cover one is lead to believe that the *Amphibians of Canada* is aimed at a general adult audience. Cutsy-pooh prose and the presumption of human emotions in amphibians belie the publishers claim that this is an "indispensable guide for students, teachers, and naturalists." What is one to make of the author's confession that her pet redback salamander *(Plethodon cinereus)* ran away after becoming "very angry because I did not give him a slug that was small enough for him to eat," or her assertion that tiger salamander *(Ambystoma tigrinum)* courtship includes "love-play"? Such prepubescent silliness could be excused if the book didn't have as many inaccuracies.

Some conspicuous errors are the claims: that "only frogs, toads, and salamanders are true amphibians." (p. 20); that salamanders in contrast to anurans have "short little tongues . . . which serve more as organs of scent than as means to catch food" (p. 35) and that "with the exception of British Columbia's Tailed Toad" *(Ascaphus Truei)* . . . "fertilization takes place externally in frogs and toads" (p.

37). (See Lombard and Wake, 1977 for a lead to the literature on tongue protrusion in plethodontid salamanders and Townsend *et al.* 1981 for a recent reference on internal fertilization in *Eleutherodactylus.*)

The *Amphibians of Canada* has neither keys nor range maps, but does have a short list of references. Included are some classics, like Logier's 1952 book and his 1955 monograph with G. C. Toner; however, other important references, such as J. S. Bleakney's 1958 zoogeographic treatise on the amphibians and reptiles of Eastern Canada, are not mentioned. A few species are neither illustrated nor described in this self-proclaimed "comprehensive book". A table purported to list all the amphibians in Canada does not properly identify *Rana clamitans.* Basic taxonomy is particularly poorly handled. Thus, for example, the reader is told that all frogs and toads belong in the order Salientia but, thereafter, only the ordinal name "Anura" is used and there is no explanation for the naive that Anura equals Salientia.

Most, if not all, of the problems in this book could have been avoided if the manuscript had been critically reviewed by a few professional herpetologists. One senses, however, some displeasure with academic herpetologists on behalf of Ms. Froom since she fills a lot of space chiding research and educational institutions for what she feels is an excessive use of amphibian specimens. I can not agree with her that plastic models could and should replace real biological materials in anatomical instruction.

If there is antagonism between amateur and professional herpetology in Canada this is regrettable, for their all-out collaborative effort may be necessary in areas such as lobbying for legislation on acid rain. Amphibian eggs and embryos are particularly sensitive to low pH (Pough and Wilson, 1977). Canada's acid rain problem is severe and of international scope since Canada catches corrosive winds blown north from the United States.

With so much to deal with and still so few herpetologists in Canada, good communication between professional and amateur herpetologists is essential. Hopefully, these two groups will work more closely in the future.

SSAR SILVER ANNIVERSARY COMMEMORATIVE

As part of the 25th Anniversary Celebration the Society has issued a beautiful *full-color* print of a Gila monster, taken from a watercolor drawing by the noted wildlife artist David M. Dennis. The print measures 11½ by 15¼ inches (29 by 38.5 cm) and is printed on a very heavy acid-free paper stock so that it can be framed or used as a poster.

The edition is strictly limited to 1000 copies, most of which were distributed at the Annual Meeting in Raleigh in August, but some copies remain for sale on a first-come, first-served basis. Prices are $10 each postpaid, or $8 each in quantities of 10 or more. Send orders to Dr. Douglas H. Taylor, SSAR Publications Secretary, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. Checks should be made payable to "SSAR"; payment in U.S. funds, please. ●

NEWSNOTES

1983 HOBART F. LANDRETH RESEARCH FELLOWSHIPS

FELLOWSHIP AWARDS: Continuing a program initiated in 1978, the Oklahoma Zoological Society and the Oklahoma City Zoo will offer four Hobart F. Landreth Research Fellowships for 1983. Each fellowship runs for 12 weeks and carries a stipend of $1,200. Limited living and kitchen accommodations are available for research fellows on zoo grounds. Library facilities are available at the zoo, and at the University of Oklahoma.

FELLOWSHIP APPLICATIONS: All applications will be reviewed by the zoo staff and the fellowship committee of the Animal Research Council. Awards are competitive and will be based on 1) scientific significance; 2) feasibility and relevance to the zoo; and 3) the investigator's academic record. Projects may be scheduled to begin at any time of the year, may be species-specific or broadly comparative, and need not be exclusively behavioral, as all aspects of zoo biology are encouraged. Originality, objectivity and applicability are major considerations for selection.

DEADLINE: Applications must be received by 15 January 1983. Notification to applicants will be made by 20 February 1983.

APPLICANT RESPONSIBILITIES: Selected Landreth Fellows are responsible for preparing a summary report of their research in publishable form and presenting a seminar to the Animal Research Council at the end of their tenure.

HOW TO APPLY: While proposals are not intended to be exhaustive documents, they should provide sufficient information for members of the reviewing committee to decide the following:

1. Significance of the proposed research to the scientific field, which would include a brief theoretical background and pertinent literature review.
2. A list of major objectives and a reasonably detailed proposal which you propose to pursue, including your methodology, experimental design, schedule (estimated starting and completion dates) and appropriate references.
3. Attach a resume of your academic background, your research experience and a letter of recommendation from a professional in your research field who is willing to serve as your adviser on this project.

Submit three copies of your research proposal along with the appropriate documents to Dr. Ronald L. Tilson, Research Curator, Oklahoma City Zoo, 2101 N.E. 50 Street, Oklahoma City, OK 73111. Telephone: (405) 424-3344. ●

SMITHSONIAN PROGRAMS OF RESEARCH TRAINING

The Smithsonian Institution announces its program of research training in higher education for 1983-1984 in the fields of American

History and Material Culture, History of Art, History of Science and Technology, Earth Sciences, Anthropology, and Biological Sciences.

Smithsonian Fellowships are awarded to support independent research in residence at the Smithsonian related to research interests of the Institution's professional staff and using the Institution's collections, facilities, and laboratories. Six- to twelve-month pre- and postdoctoral fellowship appointments and ten-week graduate student appointments are awarded.

Applications are due January 15, 1983. Stipends supporting these awards are: $17,500 per year plus allowances for postdoctoral fellows; $10,500 per year plus allowances for predoctoral fellows; and $2,000 for graduate students for the ten-week period of appointment. Pre- and postdoctoral stipends are prorated on a monthly basis for periods less than one year.

Awards are based on merit. Smithsonian Fellowships are open to all qualified individuals without reference to race, color, religion, sex, national origin, age, or condition of handicap of any applicant. For more information and application forms, please write: Office of Fellowships and Grants, 3300 L'Enfant Plaza, Smithsonian Institution, Washington, D.C. 20560. Please indicate the particular area in which you propose to conduct research and give the dates of degrees received or expected. ●

HERPETOLOGICAL PUBLICATIONS AVAILABLE

Two publications of interest to herpetologists have recently been published by the U.S. Fish and Wildlife Service:

Bury, R. B. (ed.). 1982. North American tortoises: conservation and ecology. U.S. Fish and Wildlife Service, Wildl. Res. Rep. 12. 126 pp.

Scott, N. J., (ed.). 1982. Herpetological communities: a symposium of the Society for the Study of Amphibians and Reptiles and the Herpetologists' League, August 1977. U.S. Fish and Wildlife Service, Wildl. Res. Rep. 13. 239 pp.

They may be ordered free of charge from the Publications Unit, Department of the Interior, U.S. Fish and Wildlife Service, 18th and C St. NW, Washington, D.C., 20240, as long as supplies last. ●

ASC MOVES TO REACH MORE SYSTEMATISTS

The Association of Systematics Collections, which has worked for a decade to promote the interests of systematics, is moving towards a wider representation of this field to present a broader, more cohesive front to government, funding sources and the public. ASC's interdisciplinary Council on Systematics and Evolutionary Biology has prepared a report (published in *ASC Newsletter* 10(4):38-40, August 1982) that strongly endorses amendment of ASC Bylaws to provide for membership of individual systematists at non-member institutions; thus, membership would be open to the bulk of the systematics community. In anticipation of the acceptance of this recommendation, *ASC Newsletter* will be available on a subscription basis beginning in 1983. Subscriptions (which will include the planned member's discount privilege on many ASC publications) will be at the proposed dues rate of $15.00 annually ($12.00 for students)—U.S. funds only, please. *ASC Newsletter* (edited by George Pisani) publishes a diverse range of notes, book reviews and articles of interest to the systematics community. Herpetological articles on collection management, color preservation, important yet poorly known collections, legislation, museum computer projects and similar topics are welcomed.

For further information, or to subscribe, write to:

Museum of Natural History
University of Kansas
Lawrence, KS 66045

or, call (913) 864-4867. ●

MONITO GECKO LISTED AS ENDANGERED

The U.S. Fish and Wildlife Service has determined that the Monito gecko, *Sphaerodactylus micropithecus,* known only from Isla Monito in the Commonwealth of Puerto Rico, is an Endangered Species under provisions of the Endangered Species Act of 1973, as amended. This action is being taken because of the extremely small population size coupled with suspected predation by rats. In addition, the Service determines that the entire island of Monito be declared Critical Habitat. All provisions of Sections 7 and 9 of the Act would now apply to this species. This rule became effective on November 15, 1982.

Questions concerning this action may be addressed to Director (OES), U.S. Fish and Wildlife Service, Washington, D.C. 20240.

FOR FURTHER INFORMATION CONTACT: Mr. John L. Spinks, Jr., Chief, Office of Endangered Species, U.S. Fish and Wildlife Service, U.S. Department of the Interior, Washington, D.C. 20240 (703/235-2771) or the Endangered Species Staff of the Service's Regional Office, Richard B. Russell Federal Building, 75 Spring Street, S.W., Atlanta, Georgia 30303 (404/221-3583).

NEW ZEALAND HERPETOLOGY

Proceedings of a 1980 symposium

This volume is a collection of 27 papers and transcripts of the ensuing discussions. Research work is reviewed, research and management needs discussed and priorities for research identified. Four papers cover New Zealand amphibians, both native *Leiopelma* species and introduced *Litoria* species. Ten papers address the tuatara *Sphenodon punctatus,* topics covered include current distribution, water relations and excretion, locomotion, thermoregulation, ecology on Stephens Island and breeding in captivity. Eleven papers deal with New Zealand lizards: taxonomic issues (7 papers), ecological studies (3 papers) and a physiological investigation. The list of parasites recorded from New Zealand reptiles is updated, and the role of New Zealand amateur herpetologists is reviewed.

Price NZ $25.00 includes packing and postage (overseas: surface mail only). Orders should be sent to: The Accountant, Department of Internal Affairs, Private Bag, Wellington, New Zealand. Please make cheques payable to: Department of Internal Affairs. ●

AMERICAN MUSEUM ANNOUNCES 1982 AWARDS TO 143 SCIENTISTS

The American Museum of Natural History has awarded grants to 143 scientists from three major funds: The Frank M. Chapman Memorial Fund, the Lerner-Gray Fund for Marine Research and the Theodore Roosevelt Memorial Fund.

"We are proud to assist so many scientists beginning their careers in the natural sciences," said Museum Director Thomas D. Nicholson in announcing the awards. These funds provide financial assistance primarily to graduate students or persons who have recently earned their doctorate degrees. Fifty-seven ornithologists received Chapman awards, 43 marine researchers were given Lerner-Gray awards, and 43 scientists received Roosevelt awards for work in entomology, herpetology, ichthyology, invertebrates, mammalogy and vertebrate paleontology.

The 5 herpetological projects funded from the Theodore Roosevelt Memorial Fund are:

"The population biology of two species of hybridizing tree frogs." Guy D. Walton, Tuskegee Institute, Alabama.

"Sexual selection and mating system variation in the Great Plains toad and Woodhouse's toad of Arizona." Brian K. Sullivan, Arizona State University, Tempe.

"Analysis of ecological correlates of exercise physiology among Panamanian frogs." Theodore L. Taigen, University of Connecticut, Storrs.

"A non-fatal immunological technique for sexing sea turtles." Debra Dick, Florida International University, Miami.

"The maintenance of pattern polymorphism in Lake Erie Watersnakes." Richard B. King, Purdue University, Indiana. ●

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

REPRODUCTION IN CAPTIVE *HELODERMA SUSPECTUM*

Several authors have commented on reproduction in *Heloderma suspectum* (Bogert and Del Campo, 1956, for a prior review; Gates, 1956; Shaw, 1964; Funk, 1966; Tinkham, 1971; Wagner *et al.*, 1976; Anon., 1980). This paper will deal with successful reproduction of *Heloderma suspectum cinctum* at the Houston Zoological Gardens in 1979.

MATERIALS AND METHODS

Five specimens of the banded gila monster, *Heloderma suspectum cinctum* were obtained from various sources from 1970 to 1978. Collecting data were not available. The lizards were kept in a glass-fronted exhibit 130x 88x140 cm. The substrate was river sand. Rocks, plastic foliage and a tree stump provided cover. A glass water dish 30x20x5 cm was provided in which the lizards could soak. Light was provided by two 40W Vita-lites® (Duro-Test Corp.). No basking spots were available. The lizards were exposed to a 20W fluorescent sun lamp (Westinghouse Corp.) 15-20 minutes every day to provide additional ultraviolet light. While on exhibit the lizards were exposed to a 14L:10D photoperiod. Average temperature was 28° C. Each lizard's diet consisted of three or four freshly killed 30g mice per month. The mice were occasionally dipped in egg yolk. One year prior to observed copulation it was thought that the lizards were obese, therefore their food intake was restricted to the above amount.

The lizards were hibernated in a metal stock tank 217x76x760 cm. The substrate was river sand, with rocks to provide cover. Water

was available in a small glass bowl to prevent soaking, for it was feared respiratory problems would occur. The specimens exhibited increased aggression toward their keeper in both years during hibernation.

The hibernation cycle began at 25° C and a photoperiod of 12L:12D 7 December 1979. Over a three week period the temperature and photoperiod were gradually decreased to 13° C and 8L:16D respectively. These conditions were held constant until 28 February 1979 when the temperature and photoperiod were gradually raised to 25° C and 14L:10D respectively by 15 March 1979. The specimens were returned to their exhibit 18 March 1979.

Eggs were placed in a clear plastic container 33x16x8 cm containing Vermiculite® and water (Tryon, 1975). A mixture of one part water to four parts Vermiculite® was used. This was drier than the mixture used by Tryon (1975), as it was felt the eggs needed less moisture than that of other reptile eggs. Wagner, *et al.* (1976) expressed the opinion that *Heloderma suspectum* eggs may need less moisture than other reptile eggs and Anon. (1980) also reported incubating *Heloderma suspectum* eggs in a drier medium than other reptile eggs. Our eggs collapsed and required several mistings to maintain their turgor. The incubation temperature was 28° C.

RESULTS AND DISCUSSION

Sexing the zoo's *Heloderma suspectum cinctum* was difficult. Wagner *et al.* (1976) mentioned probing (Laszlo, 1975), and Tinkham (1971) suggested comparing several characteristics in order to determine sex, including differences in scalation, size dimorphism, shorter claws on forefeet of males, tail more tumid and shorter in females than males, and lateral postanal areas on the ventral side showing hidden peni. In the zoos lizards, probing was inconclusive, and dimorphic differences were not noted in scalation or physical appearance. I eventually sexed our lizards by observing copulation and egg laying. Lengths, weights and sexes are presented in Table 1.

I observed copulation involving male A and female B 27 April 1979 and again on 6 May 1979. Copulation in nature has been reported in July (Ortenburger, 1924; Ortenburger and Ortenburger, 1926). In captivity it has been reported in May (Shaw, 1964) June and September (Gates, 1956), December, January, March and May (Wagner *et al.* 1976) and June (Potter, pers. comm.). Copulation in the zoo's lizards lasted 40 min-1 hr. Gates (1956) reported copulation lasting almost 30 minutes, Wagner *et al.* (1976) reported three, five and 15 minutes. Potter (pers. comm.) reported 20 minutes. The copulatory position of the zoo's lizards were identical of that described by Gates (1956) and Wagner *et al.* (1976).

On 31 May 1979 while in a holding pen, female B laid a clutch of four eggs (70x33 mm, 49.6 g; 64x32 mm, 39.9 g; 59x29 mm, 31.1 g; 69x31 mm, 44.0 g). On 14 June 1979 female A laid an egg in the exhibit. The following day a second egg was deposited. Measurements of the eggs were 58x33 mm, 34.4 g; and 55x30 mm, 30.6 g. One egg was found in a crevice in the tree stump and the other was lying on the sand. The eggs laid in the exhibit by female A appeared to be unmolested. Bogert and Del Campo (1956) cited *Heloderma suspectum* eggs apparently eaten by adult lizards, and Shaw (1964) also noted that *Heloderma suspectum* will eat their eggs. Dates of oviposition, number, size and weight of eggs recorded in the literature are given in Table 2.

On 30 September, after an incubation period of 122 days, a slit appeared in an egg laid by female B. Since the lizard had not emerged from the egg by the following day, it was gently removed. It was 121 mm snout-vent length, 187 mm total length, and weight was 31.0 g. It was not known from which of four eggs laid by female B this hatchling emerged.

The second egg to hatch was one of two laid by female A. Since no record was kept of which egg was laid which day by female A, the incubation period was 112 or 113 days. The hatchling had a great deal of yolk to be absorbed, as well as a very bloated abdomen, spindly limbs, poor motor control, and a tail greatly reduced in length and girth compared to the first hatchling. It was 90 mm snout-vent length, 105 mm total length, and weight was 23.0 g. After one day it died, was preserved and deposited in the vertebrate collection of The University of Texas at Arlington. Shaw (1964) noted an incubation period of 117 days in one case, noting the hatchling had a great deal of yolk to be absorbed, which led him to believe the lizard hatched prematurely.

The third egg to hatch was also one of four laid by female B. The hatchling slit the shell and emerged 4 October 1979, after incubating 126 days. Snout-vent length was 125 mm, total length 191 mm, and weight 37.0 g. Data previously recorded in the literature concerning incubation period of eggs and hatchling size are given in Table 3.

Ground color of the zoo's hatchlings was milk white as opposed to yellow or orange and no significant pattern difference was

Table 1. Sex, Size and Period in Captivity of *Heloderma suspectum cinctum.*

	Weight (g)	Length (mm)	In Captivity
Female A	362	270 SV, 410 Total	3 years, 2 months
Sex unk.	514	290 SV, 415 Total	3 years, 2 months

noted between them and the adults. The hatchlings' white ground color gradually turned yellowish and at the time of this writing (20 July 1980) are pink-tinged. Ditmars (1936) stated that hatchlings are more vividly colored than adults, while Shaw (1964) indicated hatchlings patterns are less reticulated. Tinkham (1971) also mentioned hatchlings having a less reticulated pattern, noting the color being yellowish and black. He further stated that many adult *Heloderma suspectum* are pink or orange and black when freshly caught, but seem to fade after being in captivity a number of years. I have seen no color loss in the zoo's adult lizards.

Of the other three eggs, one severely desiccated and was discarded, one mildewed and was discarded, and the third was thought dead, was opened, and contained a decomposed embryo. The dead embryo was neither measured or preserved.

ACKNOWLEDGMENTS

I am grateful to Hugh R. Quinn, Bern W. Tryon and the staff of the Department of Herpetology of the Houston Zoological Gardens for assistance rendered.

CHARLES W. GILMORE'S
FOSSIL LIZARDS OF NORTH AMERICA

In honor of the 50th Anniversay in 1978 of the first edition of Charles W. Gilmore's FOSSIL LIZARDS OF NORTH AMERICA, the Riverside Museum Press made this classic monograph available again to the scientific community. Originally published by the National Academy of Sciences in 1928 as Scientific Memoir 22, it stands as one of the most important works in the area of systematic paleoherpetology and serves as a valuable reference for both the herpetologist and the paleontologist.

This monograph covers all North American lizard families and gives complete oesteological accounts of the various genera and species (exclusive of Mosasauridae) up to 1928. This new edition provides an introduction by Dr. Richard D. Estes summarizing the advances in paleoherpetology during the past 50 years. FOSSIL LIZARDS OF NORTH AMERICA is reprinted in its original size with all plates and figures illustrated as in the original. This reprint comes in a handsome hardcover to insure many years of utility.

PRICE: $24.95 plus $2.00 shipping & handling (Calif. residents add 6% sales tax).
INSTITUTIONAL DISCOUNT: 10% off ($22.45 + $2.00 shipping & handling)for Museums, Libraries, and Schools.
BOOKSELLERS DISCOUNT: 10 or more copies - 40% off ($14.97 ea. + shipping costs).
NOTE: Please include your sales permit number with your order. Billing terms: Payment with order or within 30 days of receipt of books.
FOREIGN ORDERS: Payment must be in U.S. funds and include sufficient ammount for overseas shipment.

COMMERCIAL FEED FROGS AS A SOURCE OF TREMATODE INFECTION IN REPTILE COLLECTIONS

Heavy infestations of digenetic trematodes can be associated with the deaths of reptile and amphibian-eating snakes in captivity. A recent review of this phenomenon at the Baltimore Zoo revealed that snakes hatched and reared in captivity were being infected by trematodes. Studies were undertaken to determine if commercially purchased feed frogs were a source of these infections, and what effect freezing of the frogs would have on the viability of the infective cysts.

Feed frogs, *Rana pipiens,* were obtained from a commercial source. They were held under refrigeration in glass containers with moist paper toweling for the initial study. Frogs were frozen for the second study by individually wrapping them in plastic bags. They were then placed in the freezing compartment of a standard household refrigerator.

In the initial study, five pithed and five recently dead frogs were dissected. The thigh muscles were removed and spread on a glass Petri dish with several drops of saline. This preparation was then mashed by another Petri dish and examined under a 10 power stereo dissecting scope, using transmitted light. The presence of cysts or migrating young flukes (marita) and their viability was determined.

In the second study, two groups of ten frogs were frozen and then thawed under refrigeration 24 hours and 10 days after being placed in the freezer. Two additional groups of 12 frogs were frozen and thawed similarly, 60 hours and 72 hours after placement in the freezer. All frogs were examined using the same techniques as the first study to determine if the frog was infected with trematodes. No attempt was made to quantitate the infection in a single frog. A frog was considered infected or uninfected on the basis of examination of the thigh muscles. Differences in cyst and marital morphology suggested that more than one species of trematode were present in the frogs. Only the percentage of living versus dead organisms was determined.

The first study with live and recently killed frogs revealed viable trematode cysts in 50% of the frogs. It was interesting to note that while the trematodes remained firmly encysted in the live frogs examined, the trematodes in the recently dead frogs had unencysted and were highly motile. These unencysted trematodes were most numerous in the subcutaneous tissues and fascial planes rather than in the muscle tissue itself.

The second study confirmed the first study. Infected frogs were found in all groups. At 24 hours both live cysts and free moving trematodes were seen. At 60 hours, 72 hours and 10 days only dead parasites were encountered. (Table 1)

DISCUSSION

Commercial feed frogs are a possible source of trematode infections in frog-eating snakes. Infected frogs were found in all groups. The actual percentage of infected frogs is probably higher than indicated by our study, since only the rear legs were examined for cysts. Close examination of the entire frog including the internal organs would have assuredly revealed a higher percentage of infected frogs (Reichenbach-Klinke and Elkan, 1965).

A standard kitchen refrigerator's freezing unit was used to test methods readily available to most reptile keepers. Time periods used in this study were not based on the time the frog was actually frozen. The end points of placing the frog in the freezer and removing it for thawing are much easier to monitor than actual freezing times. Some variation in the speed of freezing should be expected depending on the age and condition of the freezer used.

The unencystment of trematodes at the death of frogs is worthy of note. It is thought that young trematodes unencyst by the digestion of the cyst wall by the new hosts' digestive enzymes (Georgi, 1974). This study provides evidence that the death of the intermediate host and not necessarily digestive enzymes triggers unencystment for at least some trematodes. This could have important implications on the possibility of trematode infection of abnormal hosts.

Of practical importance, this study indicates that conversion of frog-eating snakes to dead food and the freezing of feed frogs for at least 60 hours prior to use should significantly reduce if not eliminate trematode transmission. It suggests the need to study the role of feed snakes in the transmission of trematodes to ophiophagus reptiles.

Table 1. The occurrence of trematode cysts in *Rana pipiens* and their susceptibility to freezing conditions over various time periods.

Trial	N	Number infected	% live cysts & trematodes
Live and recently killed frogs	10	5	100%
Frogs frozen 24 hours	10	5	100%
Frogs frozen 60 hours	12	11	0%
Frogs frozen 72 hours	12	7	0%
Frogs frozen 10 days	10	2	0%

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1978. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

SAURIA

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink). **REPRODUCTION.**

Collins (1975. Trans. Kansas Acad. Sci., 77:126-127) summarized four known egg clutches of this taxon, which numbered eight to eleven eggs per clutch.

On 1 May 1982 I collected a gravid female *E. a. pluvialis* under a rock in Cherokee County, Kansas, (Sec.10, T35S, R25E) on the edge of an oak-hickory stand and osage-orange secondary growth. The skink was maintained in captivity until egg deposition, whereupon the lizard and its clutch were preserved. Unfortunately, the exact date of deposition was not recorded, but was known to be in the last quarter of May. The female (KU 192368) measured 61 mm SVL and 152 mm TL. The ten eggs (KU 192369) measured 9.0 mm to 11.0 mm in length ($\bar{x}$=9.79 $\pm$ 0.63 SD) and 6.0 mm to 7.0 mm in width ($\bar{x}$=6.15 $\pm$ 0.30 SD).

A second female (KU 192174) measured 60 mm SVL and 133 mm TL, and was collected by J. T. Collins and L. Miller on 17 April 1982 at Sec.36, T33S, R25E, in Cherokee County, Kansas, beneath a dead log. The body cavity contained nine oviducal eggs of which eight were measured (the ninth egg was damaged

on extraction and was not measured). These eggs measured 5.1 mm to 7.0 mm in length ($\bar{x}$=6.15 ± 0.62 SD) and 5.0 mm to 6.1 mm in width ($\bar{x}$=5.43 ± 0.49 SD).

Submitted by **KELLY J. IRWIN,** Animal Care Unit, University of Kansas, Lawrence, KS 66045. ●

XANTUSIA VIGILIS (Yucca night lizard). **LONGEVITY.** 0.0.3 adult specimens obtained from a California reptile dealer 22 April 1962. The death of one specimen was not recorded; the other two died 16 April 1966 and 19 June 1966; the latter surpassing the record of the Arizona Sonora Desert Museum (Bowler 1977. *Longevity of reptiles and amphibians in North American collections.* SSAR Herp. Circ., 6:1-32.) The new record of 4 years, 1 month, 27 days surpasses the old one by 3 months, 14 days.

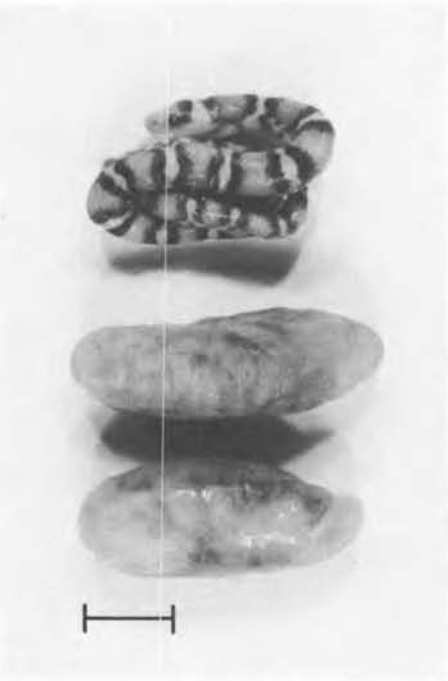
SERPENTES

CEMOPHORA COCCINEA (Scarlet Snake). **REPRODUCTION.** Anecdotal information has been published (see Fitch, 1970. Univ. Kansas Publ. Mus. Nat. Hist. 52:1-247) on the reproductive biology of the scarlet snake, *Cemophora coccinea,* and only one egg clutch has been reported (Woolcott, 1959. Copeia 1959:263). Below I present data on a second clutch.



While seeking *Cnemidophorus sexlineatus* eggs, I unearthed a clutch of three scarlet snake eggs from beneath the pine straw and humus covering the red clay soil of a south-facing embankment along a rural highway in Coweta Co., Georgia, on August 13, 1978. The eggs were not adherent and were spaced several cm apart. All were elongate, irregular in shape (Fig. 1) and off-white in color as described by Woolcott *(op. cit.).* The clutch was placed in formalin soon after collection and is currently deposited in the Georgia Southwestern College Museum (GSCM 2138-40).

Average egg measurements two and one-half years after preservation were: length x width, 34.5 mm x 12.5 mm; weight, 2.40 g, and yolk mass weight, 0.53 g. Embryo weights averaged 1.52 g (1.47 - 1.57). Snout-vent lengths averaged 111.3 mm (108.6 - 114.2), and all tail lengths were 18.0 mm. The yolk mass of each egg was dispersed so as to completely surround the embryo.

With their well documented dietary preference for reptile eggs (*e.g.,* Martof, *et al.,* Amphibians and Reptiles of the Carolinas and Virginia), it is not surprising to find scarlet snakes nesting in proximity to this potential food source. In the past, I have collected adult scarlet snakes (from Alabama, Arkansas, and Georgia) in a manner similar to that which I used in locating the present nest. Two of these snakes, incidentally, were removed from hibernation dens in red clay embankments.

I thank Dr. Robert H. Mount of Auburn University and an anonymous reviewer for their critical comments on the manuscript, and also Alfred C. Lamb, III, and Charles W. Seyle, Jr., for field assistance.

Figure 1. Eggs and an embryo of the scarlet snake, *Cemophora coccinea.* The yolk mass has been removed from the embryo. Line equals 10 mm.

Submitted by **STANLEY E. TRAUTH,** Department of Biology, Georgia Southwestern College, Americus, GA 31709. Present address: Department of Biology, Southern Methodist University, Dallas, TX 75275. ●

EUNECTES (Anacondas). **MATURATION.** The attainment of sexual maturity and its relationship to size and age in boids is little understood. Rates of growth are variable and are probably accelerated under captive situations. The second generation birth in captivity of two species of *Eunectes* at the New York Zoological Park however helps to pinpoint maturation parameters for those species.

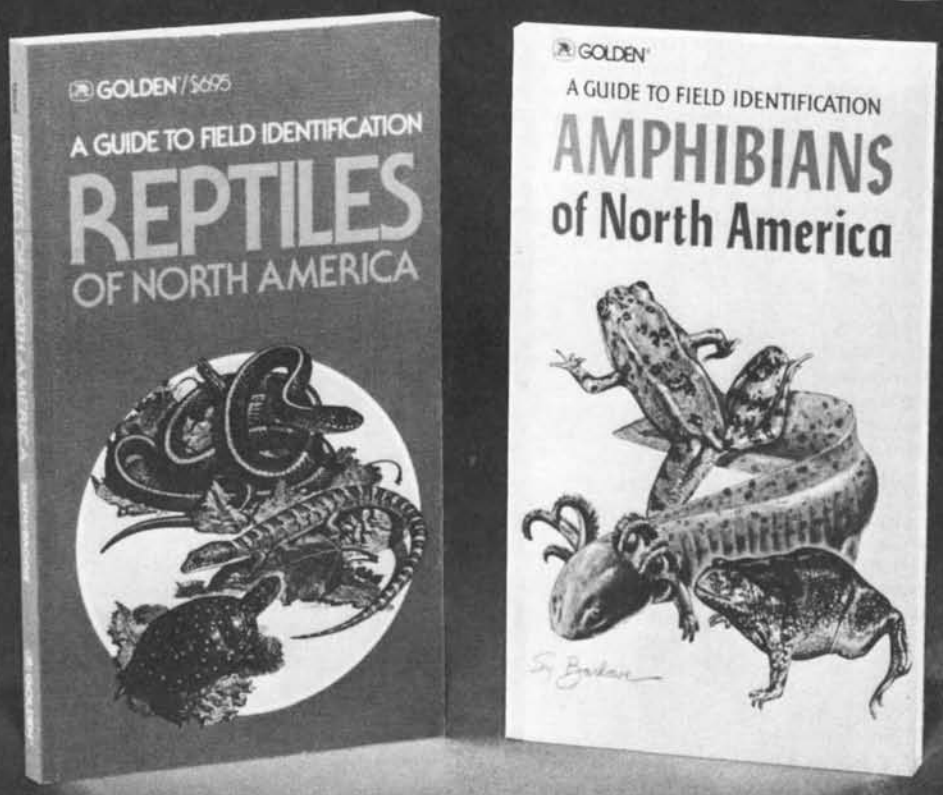
Eunectes murinus. A sibling pair of *E. murinus* born 5 February 1978 (Holmstrom, 1980, Herp. Rev. 11(2):32-33) was placed together on 2 December 1979. Courtship was noted on numerous occasions from 14 March to 4 June 1981. The pair was 3 years, 1 month, and 9 days (1133 days) of age when courtship began. On 18 July the female was evidently gravid and on 8 December 1981 she gave birth to 18 young at 3 years, 10 months, and 3 days (1402 days) of age. Her post parturient weight was 25.12 kg and she was 3.63 m in total length (=TL) and 3.16 m in snout-vent (=SV) length. At that time the male weighed 21.43 kg and was 3.53 m TL and 3.0 m SV.

Eunectes notaeus. A female E. notaeus ($♀_1$) born 29 April 1978 (Holmstrom, 1982, Int. Zoo Ybk. 21:92-94) was introduced to an adult male and two adult females of unknown origin on 10 November 1981. Courtship between the male and one of the females (parent of $♀_1$) was observed during November and December of 1981. On 17 January 1982 $♀_1$ appeared gravid. She was 3 years, 10 months, and 19 days (1390 days) of age and weighed 8.82 kg and was 2.48 m TL and 2.13 m SV. On 16 February 1982 a radiograph revealed large egg masses of uniform opacity and on 10 July 1982, at 4 years, 2 months, and 11 days (1533 days) of age, she gave birth to 18 young.

Submitted by **WILLIAM HOLMSTROM,** Department of Herpetology, New York Zoological Park, 185th St. and Southern Blvd., Bronx, New York 10460. ●

TESTUDINES

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **NESTING.** On 24 April 1981, a *Dermochelys* crawl was observed on the ocean beach of Cumberland Island, Camden County, GA. The nest cavity was not located but the site was marked and checked no less than bi-weekly during the incubation period except between 19 and 25 July. Thereafter, the site was checked daily until a single track of an emerging hatchling was observed on the 31st of July, 98 days after the nesting. At that time there were two live hatchlings at the surface of the nest so it was not excavated until 5 August. A conservative estimate of the number of eggs laid was 67, based on the number of eggs and egg shells found when the nest was excavated. From the shell fragments 10 animals were judged to have hatched, 43 eggs were undeveloped, three were partially developed, and 11 were full-term, dead in the egg. Of the estimated 10 that hatched, at least 5 were dead and decomposing in the nest, at least 3 emerged alive from the nest and 2 were not accounted for. Exceptionally high tides during the early incubation period eroded the beach to within 50 cm. of the nest, probably accounting for some mortality.



On 14 June 1981, on Blackbeard Island National Wildlife Refuge, McIntosh County, GA the nesting of a *Dermochelys* was photographed. Carapace measurements of this nesting female were: length on contour, 163 cm.; width, 112 cm. The turtle was apparently searching for a nest site when encountered at 0235 hr. and laid 89 eggs which were moved to a hatchery. Initial emergence of the hatchlings occurred on 18/19 August, after a 66 day incubation period.

Cumberland Island is approximately 95 miles north of the northernmost confirmed *Dermochelys* nesting at Flagler Beach, FL. (Carr, A. 1952, Handbook of Turtles. Comstock Pub. Assoc., Ithaca, NY. 542 pp.) and Blackbeard Island is 145 miles north. These two nestings are the first recorded for *Dermochelys coriacea* in Georgia.

Voucher specimens have been deposited in the Savannah Science Museum and the U.S. National Museum.

Submitted by **CAROL RUCKDESCHEL, LEIGH ELLIS,** and **C. ROBERT SHOOP.** Box 796 St. Marys, GA. 31558; Institute of Ecology, University of Georgia, Athens, GA. 30601; Dept. of Zoology, University of Rhode Island, Kingston, RI 02881. ●

Two Great Field Guides
From GOLDEN PRESS

Professors and students of herpetology will find these two guide books of great assistance in their work and studies.

REPTILES OF NORTH AMERICA, by Hobart M. Smith and Edmund D. Brodie, Jr., illustrated by David Dennis and Sy Barlowe. 1982 Western Publishing Company, Inc. 240 pages. $6.95 softcover, $9.95 hardcover

AMPHIBIANS OF NORTH AMERICA, by Hobart M. Smith, illustrated by Sy Barlowe. 1978 Western Publishing Company, Inc. 160 pages. $6.95 softcover, $9.95 hardcover

- Designed for ease-of-use in the field—with descriptive text, full-color illustrations, and range maps for each species on facing pages
- Authoritatively written and beautifully illustrated
- Most up-to-date field guides available
- Easy-to-use *visual* keys (standard two-choice-type keys are provided for all genera with more than 2 or 3 species, with virtually every key feature—such as scale characters—illustrated by excellent line drawings)
- Expanded text covers evolution, distribution, anatomy, reproduction, behavior and more

If REPTILES and AMPHIBIANS are unavailable from your local retailer, you can order them by sending the book(s) price, plus $1 per order for postage and handling to:

BOOK REVIEWS

Common Indian Snakes: A Field Guide, by Romulus Whitaker. 1978. xiv + 154 pp. The MacMillan Co. of India, Ltd. Price 12 Rs (postage extra).

This concise, informative and well illustrated guide provides an excellent introduction to the snake fauna of India (and adjacent SE Asia). The book deals only with the 30 most common Indian species, and contains essentially three major sections. The first is a series of accounts of non-venomous and venomous species, each following what has long served as a standard format for such accounts (English name, scientific name, description, range, etc.). The accounts are well done, and succeed in presenting a thorough profile of each species. The illustrations in this section are generally very good (as are most through the book), and those few which do not look very good (*Macropisthodon plumbicolor* — p. 21; *Dendrelaphis tristis* — p. 36) are still suitable for identification purposes. I suspect several photos would have reproduced better if more finely screened during printing. This section would have been further enhanced were it preceded by an artificial key to species constructed from the DISTINCTIVE FEATURES given for each one. Instead, a key derived from Minton (1962) is included back on page 139; this key, while good, utilizes a variety of scale characters which laymen may have difficulty discerning. In fact, Whitaker implies (p. 145) the value of the sort of key I've mentioned by stating, "Identification of the living snake in the field is usually made on the basis of colour, pattern, habitat and behaviour." I agree with him in that ". . . the clues used do not lend themselves well to brief verbal description", but a better key could have been constructed for thirty species. Oh, well; enough of being picky. The accounts are, as I've said, very well done.

The second major section, general information, is a useful potpourri of life history and anatomical features of snakes, plus brief accounts of their economic value and Indian mythology. It also includes, as a separate chapter, a very good discussion of snakebite in India.

The last section is essentially nomenclatorial, and contains a revised version of Smith's (1961) checklist of Indian snakes, a list of vernacular names for the thirty species treated in the book, and the aforementioned key from Minton (1962). The selected bibliography is thorough, but omits one of the references cited in text (Hartline, 1971) on page 74. A rainfall chart is a useful addition to the book and is in this last section.

Typography is generally good, and I saw few errors (most are handled in the Errata on the book's last page). On page 139, *Trimeresurus* is broken into two words; on page 102, hospital should be plural; on page xii about is divided in two; and throughout the text, up to is combined in one word (upto). These are presented as notations rather than criticisms, since editors quickly learn not to point derisively at the typographical errors of others!

I recommend this book highly to those interested in the Indian herpetofauna, and hope it will accomplish one of the author's objectives, to ". . . help stir up some popular interest in this group of reptiles."

Comparative Ecology of Two Colubrid Snakes in Northern Utah: *Masticophis t. taeniatus* and *Pituophis melanoleucus deserticola*, by William S. Parker and William S. Brown. Milwaukee Public Museum, Publications in Biology and Geology Number 7, 104 pp.

This outstanding treatise on snake ecology is based upon a unique combination of individual marking and recapture on a large scale, and of radiotelemetric monitoring of selected individuals. It is noteworthy for the great amount of detailed data which were gathered and analyzed, and for the thorough coverage of literature putting the original findings in perspective. Comparisons are made of every aspect of the findings concerning *Masticophis t. taeniatus* and *Pituophis melanoleucus deserticola* with whatever was known previously about these or other kinds of snakes.

Brown and Parker shared the field work in a collaborative project which yielded doctoral dissertations for both. These two workers were heirs to the snake den complexes in Tooele County, Utah, studied by Dr. Angus M. Woodbury and his students throughout the 1940s, and later investigated by Dr. Harold F. Hirth and associates. The early studies by Woodbury and his co-workers were concerned mainly with rattlesnakes (*Crotalus viridis*), but by the last decade most of the rattlesnake population had disappeared from the dens. The main species still present were the gopher snake, the striped whipsnake and the western yellow-bellied racer (*Coluber constrictor mormon*). The latter is not formally dealt with in the present report, but is often mentioned in comparison.

Like earlier studies at the Tooele County den complexes, this one involved fencing of the separate dens with mass capture and marking (by scale-clipping) of the emerging or returning snakes in spring or fall. The data base included 1264 captures of 242 whipsnakes and 411 captures of 211 gopher snakes. However, the mark-and-recapture procedures were supplemented by radio-

telemetry which was the focus of the present study. A total of 14 *Masticophis* and 10 *Pituophis* were followed for 604 cumulative snake days. The paper has the following topic headings: Acknowledgments, Abstract, Introduction, General Methods, Hibernation, Thermoregulation, Activity, Movements, Trailing Ability, Reproduction, Fat Bodies, Ecdysis, Growth, Population Dynamics, Predation, Food Habits, General Discussion. Under some of these topic headings there are several (up to 9) subheadings, including "Methods", "Results" and "Discussion". For the two kinds of snakes trinomials are used throughout in the tables and the legends for figures, but in the text they are referred to simply as *Masticophis* and *Pituophis*. Many of the figures could have been further reduced, resulting in some saving of space and neater appearance.

Among the more significant findings were the following: both whipsnakes and gopher snakes are active mostly by day, but the former tend to stay in the open and the latter under shelter. After morning basking each kind thermoregulates to keep its body temperature within a narrow range throughout the day, mean 31.2° for the whipsnake vs 27.9° for the gopher snake. Average dispersal distance from dens was about 509 m for gopher snakes of both sexes, but was 992 m for 6 male whipsnakes and 1455 m for 4 females. Polygonal home ranges plotted from recorded stations averaged 1.05 ha in male gopher snakes, 2.09 in females. Home ranges were not demonstrable in whipsnakes. Eggs of both species were laid in abandoned mammal burrows, sometimes in communal nests. Experimentally displaced whipsnakes homed over distances up to 850 m, and were consistently successful in homing over distances up to nearly 400 m. In gopher snakes homing ability was less well developed. Males of both species usually attained sexual maturity at 1 year; female gopher snakes laid their first clutches at ages 3-5, female whipsnakes were always mature at 3 years, some possibly at 2. Population density of whipsnakes was calculated as .11 to .33 per ha (biomass 14.3 - 30.9 g per ha) and for gopher snakes .32 per ha (65.4 g per ha). The den population of whipsnakes, not including first-year young, consisted of about 1/3 old adults (more than 5 years old) and two-thirds young adults and immatures. In gopher snakes the proportion of old adults was somewhat higher — above 40%. Female whipsnakes emerging from hibernation were found to move to individual areas within 200 m and remain for several days or weeks during a mating period, before the relatively long distance dispersal to summering areas. During this same spring period males were active in sexual search, and those successful in finding a female often remained with her over periods of days. During this breeding season a whipsnake of either sex might have a succession of partners, with occasional combat or pursuit, and displacement of a smaller mated male by a larger one.

Snakes from outside the study area were sacrificed to obtain information that could be gained only by dissection. In contrast to the hundreds of records obtained of movements and body temperatures, relatively few records were obtained of predation on the snakes, of food and of clutch size. Mean clutch size was 5.8(3-10) in 13 *Masticophis* and 7.4(4-10) in 9 *Pituophis*. Food items of whipsnakes included 18 lizards (12 *Uta*, 3 *Phrynosoma*, 2 *Sceloporus*, 1 *Cnemidophorus*), 2 snakes (*Masticophis, Coluber*), and 8 mammals. Small whipsnakes ate only lizards. Food of gopher snakes included 14 mammals (*Microtus, Perognathus, Peromyscus*) 1 lizard (*Uta*), and 1 grasshopper! The 4 instances of predation obtained were of 1 gopher snake taken by a Red-tailed Hawk, 1 small whipsnake eaten by a large one, and 2 whipsnakes killed by mammalian predators, probably weasels.

The Utah study will be an indispensible reference to anyone concerned with ophidian ecology. The authors and the Milwaukee Public Museum are to be congratulated.

Inventory of Reptiles and Amphibians in Captivity, 1982. Frank L. Slavens. Privately printed, July 5, 1982. 212 pp., ill. (Available from author only, P.O. Box 30744, Seattle, Washington, 98103; $20 paper, $25 hardbound, postpaid).

Single-handedly Frank Slavens of the famed Woodland Park Zoological Gardens of Seattle has issued the fifth in a series of annual compilations of live amphibians and reptiles in both public and private collections in the United States, Canada and Mexico. The first was issued in 1976, followed by editions in 1977 (not distributed), 1980, 1981 (a few still available, same price) and 1982.

The 1982 edition reports on 176 (69 public and 107 private) collections representing 382 genera, 952 species and 1352 species-group taxa extant in those collections as of January 1, 1982. The first part of the work (pp. 10-44) lists alphabetically under family and order in systematic sequence the 314 species reported to have bred in captivity during 1981 or previous years, with all available related information, such as dates of copulation, oviposition or parturition, incubation or gestation, developmental temperatures, sex ratios of neonates, *etc.*

The second part of the work (pp. 46-182) lists, in the same arrangement as in the first part, all live specimens, breeding or not, in the reporting collections, noting sexes and number of each.

A family and generic index to both parts is given in the Table of Contents (pp. vii-xv). The book terminates with a 4-page bibliography and a 6-page alphabetical list of the codes used for designation of collections. Numerous vignettes and a colored frontispiece cartoon embellish the work throughout, adding materially to the pleasure of using it either seriously or casually.

For many years European terrarists have been essentially alone in their devotion to private maintenance and propagation of amphibians and reptiles, as attested by their near monopoly on terrarist magazines and books. Partly because of the world-wide expansion of concern for conservation of threatened species, a prodigious growth of interest in care of herpetozoa in captivity has taken place in North America in the past decade or two, now approaching equivalence to the long-established European tradition.

Never before, however, has there been an attempt to list all live herps maintained in all collections of such a large area as North America. It is a unique and highly useful service to not only public and private collections in their attempts to establish strong breeding programs, but to a wide variety of experimentalists, ethologists, physiologists, etc., who are in need of examples of particular species of particular sex that would otherwise be unobtainable or obtainable only with great difficulty. Loans, gifts and exchanges are greatly facilitated by knowledge of where what exists already in captivity.

Plans are laid already for the 1983 editon, which, profiting from the experience gained the past five years and the recent acquisition of a word processor, is to be greatly expanded in scope (worldwide) and content (including a synoptic bibliography of works — books and articles — on all aspects of herpetological breeding and husbandry, and greater emphasis upon breeding information), while maintaining the current listings of inventory and reproductive data.

Participation of both private and public caretakers, even of the smallest collections, in the 1983 edition is strongly urged. Advice of works on husbandry is also solicited by the author. There is no charge for entries of any sort, and because of the attribution of data to specific coded sources, data may be cited under the name of the originator (*e.g.* an entry under (*Caiman crocodilus*, pp. 18-19 of the 1982 edition, is attributable to Pat Jacobs in Slavens, 1982, *etc.*).

Especially in the present era of well-deserved concern for the welfare of the many threatened and endangered species of herpetozoa, all biologists, ecologists and conservationists owe an enormous debt of gratitude to Slavens for the incomparable service provided by this "Inventory," produced on a shoestring, without governmental or other subsidy, by dint of heroic effort rarely paralleled in any field of endeavor. The self-sacrificial devotion required for single-handed production of this work, from solicitation and collation of data to typing, duplication and binding, is almost inconceivable, yet has not only been demonstrated repeatedly over the past six years but is anticipated with total equanimity and self-confidence at an even more rigorous level in the future, as an ongoing lifetime project. Fortunately the author is young, strong and healthy, and merits the support of the entire herpetological world in promotion of the success of his long-term goals.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

CAUDATA

BATRACHOSEPS ATTENUATUS (California Slender Salamander). USA: CALIFORNIA: Tehama Co: 0.8 km south of Williams Butte, 335 m (T23N, R6W, Sec. 8) (one specimen) and 0.4 km west of Williams Butte, 366 m (T23N, R7W, Sec. 12) (four specimens). Collected by M. R. Jennings and D. Kerwin on December 14 and 15, 1981. Verified by D. B. Wake and S. D. Busack, University of California, Berkeley. Museum of Vertebrate Zoology, U. C. Berkeley (MVZ 158894, 158895-158898). First records for Tehama County and extends the distribution of this species some 24 km north than previously reported (Yanev, K. P. 1980. Biogeography and distribution of three parapatric salamander species in coastal and borderland California. Pages 531-550 *in* D. M. Power (ed.). The California islands: proceedings of a multidisciplinary symposium. Santa Barbara Mus. Nat. Hist.). Specimens taken under logs and debris in oak woodland with chamise, mazanita, and digger pine present. Three other salamanders captured on the afternoon of December 15th were released.

Submitted by **MARK R. JENNINGS,** California Department of Fish and Game, P.O. Box 607, Red Bluff, California 96080. Present address: School of Renewable Natural Resources, 210 Biological Sciences East Building, The University of Arizona, Tucson, Arizona 85721. ●

ENSATINA ESCHSCHOLTZI KLAUBERI (Large-blotched Ensatina). USA: CALIFORNIA: San Diego Co: 4.8 km E of Ramona (by road) on State Highway 78. 27 March 1970. R. P. Yingling and C. Croulet. Verified by V. N. Scheidt and R. P. Yingling. Extends known range 21.4 km WSW. Specimen observed on road through Southern Oak Woodland habitat. Two forms of *Ensatina* occur in San Diego County — *E. e. klauberi* typically in montane coniferous habitat, and *E. e. eschscholtzi* at lower elevations, primarily in riparian oak woodland habitat. Specimen observed may have been washed downstream from typical habitat at higher elevations E of site of observation; however, since date of observation, other *E. e. klauberi* have been found in Southern Oak Woodland habitat E of this locality. Because of the restricted distribution of this form, the specimen was not collected. The specimen was photographed at the site of observation, however, and a voucher photograph is presented here in lieu of a catalogue number for verification.

Submitted by **VINCENT N. SCHEIDT,** 4434 Bannock Avenue, San Diego, California 92117, and **R. PETER YINGLING,** 6328 49th Street, San Diego, California 92120. ●

GYRINOPHILUS PORPHYRITICUS PORPHYRITICUS (Northern Spring Salamander). USA: MASSACHUSETTS: Worcester Co: 3.6 km E of Holden Center at 29 Oregon Trail, 750 m, 27 April 1982, George Ginerelli and Paul Rugg. Verified by T. E. Graham. Harvard University, Museum of Comparative Zoology (MCZ 100978). Bright salmon-red specimen (14.7 cm total length) found fully exposed beside back yard steps and retaining wall at 1130 hr. Second record for the county; extends range roughly 17 km southeast of its only previously known locality of Wachusett Mountain, Princeton (Lazell, 1974, Reptiles and Amphibians in Massachusetts, 2nd. Ed., Publ. Massachusetts Audubon Society).

PSEUDOBRANCHUS STRIATUS (Dwarf Siren). USA: FLORIDA: Walton Co: Sec 5-T2S-R18W. 9.6 air km SE Freeport. 19 May 1980. K. Thomas and P. Moler. Fla. State Mus. (UF 47165-47172). First records for county. Extends known range 90 km SW and represents the westernmost locality for *Pseudobranchus* (Martof. 1972. Cat. Amer. Amphib. Rept., 118.1)

Submitted by **PAUL E. MOLER,** Florida Game and Fresh Water Fish Commission, 4005 S. Main St., Gainesville, Florida 32601 and **KELLY THOMAS,** Rt. 2, Box 27, Florala, Alabama 36442. ●

ANURA

ELEUTHERODACTYLUS PLANIROSTRIS PLANIROSTRIS (Greenhouse Frog). USA: Alabama: Baldwin Co: Fairhope, from under masonary debris on the campus of the Marietta Johnson School of Organic Education. 11 April 1982. S. D. Carey. Identified by S. D. Carey. Auburn University Museum (AUM 30914). Striped phase female (SVL 31 mm) with mature ova. This is the first record of this subspecies in Alabama. Observations at this location in September 1982 revealed both striped and mottled phase individuals, and numerous juveniles.

Submitted by **STEVEN D. CAREY,** Department of Natural Sciences, Mobile College, P.O. Box 13220, Mobile, Alabama, 36613. ●

HYLA GRATIOSA (Barking Treefrog). USA: Maryland: Caroline Co: collected 1.1 km east of Henderson on Bee Tree Road. 18 June 1982. K. Anderson and H. G. Dowling. New York University (HGD 74875). Verified by K. Anderson and H. G. Dowling. Adult female with immature ova found on dirt road between two bean fields. Head width/tibio-fibula length = 0.831. Individual in desiccated condition. This represents the first published record of *H. gratiosa* in Maryland. Known range extends north to the mouth of Chesapeake Bay, in southeastern Virginia (Conant, 1975. A Field Guide to the Amphibians and Reptiles of Eastern and Central North America. Houghton Mifflin Co., Boston). Specimen may be a member of a small relict population, part of an unreported introduced sample, or represent an individual release event. Field studies supported in whole by BRSG Grant RR07062 awarded by the Biomedical Support Grant Program, Division of Research Resources, NIH to HGD and KA.

LIMNAOEDUS OCULARIS (Little Grass Frog). USA: FLORIDA: Bay Co: Sec 27-T1S-R15W. 23 June 1980. (UF 47376-47377). Washington Co: 1) Fla. Hwy 284, 5.6 km N jct. Fla. Hwy 284A. 2 Aug. 1979. (UF 45286); 2) 4.5 km N Hinson's Cross Roads. 2 Aug. 1979. (UF 45287). Walton Co: 1) Fla. Hwy 20, 0.8 km E Bruce. 24 May 1979. (UF 45190-45191); 2) Fla. Hwy 282 at Alaqua Creek. 4 July 1979. (UF 45285); 3) Fla. Hwy 20. 0.5 km W Basin Bayou. 27 June 1980. (UF 47378); 4) Fla. Hwy 20, 7.2 km E Walton-Okaloosa Co. line. 27 June 1980. (UF 47379). P. Moler. All specimens Fla. State Mus. First records for each county. Extend known range 75 km SW. (Franz and Chantelle. 1978. Cat. Amer. Amphib. Rept. 209.1).

Submitted by **PAUL E. MOLER,** Florida Game and Fresh Water Fish Commission, 4005 S. Main St., Gainesville, Florida 32601. ●

RANA PIPIENS (Northern Leopard Frog). USA: MINNESOTA: Winona Co: Bob Virchota Landing, Mississippi River near Winona (T 107N, R 7W, Sec. 7). 25 September 1974. P. A. Cochran. Bell Mus. Nat. Hist., Univ. Minnesota (10842). First published record for Winona County (Breckenridge, 1944, Reptiles and Amphibians of Minnesota, Univ. Minnesota Press; Minnesota Dept. of Natural Resources, 1979, Guide to the Reptiles and Amphibians of Southeast Minnesota - Region 5). Leopard frogs were also observed at this site 10 May 1980.

Submitted by **PHILIP A. COCHRAN,** Laboratory of Limnology, University of Wisconsin, Madison, Wisconsin 53706. ●

TESTUDINES

STERNOTHERUS CARINATUS (Razorback Musk Turtle). USA: ARKANSAS: Pike Co: Little Missouri River at Ark. Hwy. 84. 4 October 1969, 11 June 1970. R. McKown and D. Brooks. West Texas State University Museum Natural History (WTSU 447, 448, 1089). Only one previous specimen recorded from this county (H. G. Dowling, 1957, Occas. Papers Univ. Ark. Mus. 3, 51p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016. ●

STERNOTHERUS ODORATUS (Stinkpot). USA: ARKANSAS: Crawford Co: Lake Ft. Smith. 30 June 1973. F. C. Killebrew. West Texas State University Museum of Natural History (WTSU 7028). Verified by F. C. Killebrew. New county record. Extends range 100 km S of nearest locality in Washington County (H. G. Dowling, 1957, Occas. Papers Univ. Ark. Mus. 3, 51p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016. ●

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). USA: ARKANSAS: Searcy Co: *ca.* 5 km S St. Joe on St. Rt. 65. 10 May 1982. Collected by Thomas Vance and G. W. Stratton, Corsicana, Texas. Verified by Thomas Vance. The specimen is deposited in the preserved specimen collection at Navarro College (NC 1982.5.12.1Tu), is one of several sighted, and is the first record for Searcy County which helps fill the hiatus in its Arkansas range. (Dellinger and Black, 1938, Occ. Pap. Univ. Ark. Mus., 1:3-47; Schwardt, 1938, Univ. Ark. Exptl. St., 357:2-47; Dowling, 1957, Occ. Pap. Univ. Ark. Mus., 3:4-51).

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

SAURIA

ANOLIS EQUESTRIS (Knight Anole). USA: FLORIDA: Monroe Co: Mile Marker 87.5, US Highway 1, Plantation Key. Summer 1981. J. Scurlock. Fla. State Mus. (UF 52748). First record for county. Approx. 60 km SW of nearest reported locality on Elliott Key, Dade County (L. D. Wilson and L. Porras. The ecological impact of man on the south Florida herpetofauna. *In Press*).

Submitted by **KAREN L. ACHOR,** 116 S. Bay Harbor Drive, Key Largo, Florida 33037 and **PAUL E. MOLER,** Florida Game and Fresh Water Fish Commission, 4005 S. Main St., Gainesville, Florida 32601. ●

HELODERMA SUSPECTUM CINCTUM (Banded Gila Monster). USA: CALIFORNIA: San Bernardino Co: 45 km NW of Needles at Piute Creek (Fort Piute). 9 May 1982. A. K., R. A. and E. G. Curran. Specimen photographed - not collected. Verified by James Bicket. Individual observed in streambed among vegetation and ground litter. Dominant plant assemblage: *Salix* sp., *Prosopis* sp., *Tamarix* sp. and *Baccharis viminea*. First verified record of this subspecies for the Piute Range, San Bernardino County, California. A substantial distributional gap exists for this subspecies in southeastern California.

Submitted by **JAMES C. BICKET,** U.S. Bureau of Land Management, Box 305, Needles, California 92363. ●

SERPENTES

NERODIA SIPEDON (Northern Watersnake). USA: MINNESOTA: Carver Co: Dead on U.S. Highway 169 just north of Minnesota River crossing into Shakopee. 2 June 1979. P. A. Cochran. Bell Mus. Nat. Hist., Univ. Minnesota (10848). First published record for Carver County (Breckenridge, 1944, Reptiles and Amphibians of Minnesota, Univ. Minnesota Press; Minnesota Dept. of Natural Resources, 1979, Guide to the Reptiles and Amphibians of Metropolitan Minnesota - Region 6).

Submitted by **PHILIP A. COCHRAN,** Laboratory of Limnology, University of Wisconsin, Madison, Wisconsin 53706. ●

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: MINNESOTA: Fillmore Co: Dead on trail about 15 m southwest of the confluence of Canfield Creek (= South Branch Creek) and the South Branch of the Root River (T 102N, R 12W, Sec. 24). 29 June 1980. R. Newman. Bell Mus. Nat. Hist., Univ. Minnesota (10850). First published record from Fillmore County and only second record from southeast Minnesota (Breckenridge, 1944, Reptiles and Amphibians of Minnesota, Univ. Minnesota Press; Minnesota Dept. of Natural Resources, 1979, Guide to the Reptiles and Amphibians of Southeast Minnesota - Region 5).

Submitted by **PHILIP A. COCHRAN,** Laboratory of Limnology, University of Wisconsin, Madison, Wisconsin 53706. ●

A RANGE EXTENSION FOR *CROTALUS MOLOSSUS NIGRESCENS* IN TAMAULIPAS, MEXICO

Crotalus molossus nigrescens is chiefly a resident of temperate pine-oak forests of Mexico's Central Plateau (Murphy, 1979). Klauber (1972) lists the range of *C. m. nigrescens* as the tableland of Mexico from southern Sonora, southwestern Chihuahua, and southern Coahuila, south and east through Durango, Zacatecas, Aguascalientes, western San Louis Potosi, Guanajuanto, Queretaro, northwestern Hidalgo, northern Michoacan, Mexico (state) Distrito Federal, east-central Veracruz and southeastern Puebla. He lists eastern Jalisco, Morelos, Tlaxcala and northern Oaxaca as problematic areas. Gloyd (1940) lists the range of *C. m. nigrescens* as throughout the highlands from southern Chihuahua, northern San Luis Potosi and southern Nuevo Leon, south to northern Oaxaca and western Veracruz. He lists southern Nuevo Leon as an area of intergradation between *C. m. molossus* and *C. m. nigrescens*.

On 7 August 1979 a male *C. m. nigrescens* measuring one meter in length was observed at 2000 hours crossing a caliche road from west to east. This locality was 7 km north of Pamillas, Tamaulipas, on the road to Miquihauna, Tamaulipas, at an elevation of 1,280 meters. The habitat type was arid tropical scrub as defined by Leopold (1950). On the morning of 8 August 1979, at 1000 hours a second male specimen was collected among the broken rock and Coyotillo (*Karwinskia humboltiana* (R&S) Zucc.) at an elevation of

2,286 meters. A third male specimen was collected at 0100 hours on 9 August at an elevation of 2,377 meters.

All three specimens were found on the base or lower elevations of hills with a southeastern exposure. Martin (1958) states that he obtained a specimen of *Crotalus durissus totonacus* in an open oak-pine woodland near La Joya de Salas where *Crotalus molussus* might be expected instead; however, he does not list *C. molussus* as occurring in the cloud forest at Rancho del Cielo, Tamaulipas. Barbara Warburton (pers. com., 1980) observed *Crotalus molussus* in early April 1961 at Rancho del Cielo at an elevation of 1,524 meters. Similarly, L. O. Sorenson (pers. com., 1980) observed specimens which he identified as *Crotalus molossus* at an elevation between 1,372 and 1,524 meters in a cloud forest in an area which had earlier been denuded by fire. Unfortunately, no voucher specimens are available from this locality, but both of the aforementioned individuals are familiar with *Crotalus durissus totonacus* and *C. molussus*.

Both the coloration and pattern characters of all three of our specimens were very different from each other. The ground color of the first specimen was dark rust with darker brown diamond markings with a nearly pure black crown. The second specimen was overall a creamy ground color with cinnamon-colored diamonds which interchanged with crossbands several places on the body. The third specimen possessed a creamy yellow ground color with a combination of burnt sienna-colored diamonds and diamond crossbands. The pattern variation of these three specimens exhibits characters of both *C. m. molossus* and *C. m. nigrescens*, and I feel that these specimens are intergrades like those found near Galeana, Nuevo Leon earlier described by Gloyd (1940).

Our three specimens from Miquihauna establish *C. m. nigrescens* as occurring in Tamaulipas, and there is strong evidence that it occurs in the cloud forest of the Gomez Farias Region of Tamaulipas as well.

Distributional Records for Mexican Reptiles

These records of occurrence of Mexican reptiles are based on specimens in the Laboratory for Environmental Biology, The University of Texas at El Paso (UTEP). All verification of identifications is by the author. All specimens were collected by the author unless otherwise noted.

PHYLLODACTYLUS LANEI RUPINUS. JALISCO: Isla Cocinas, Bahía de Chamela, ca. 4 km WNW (offshore) Chamela, 22 July 1976, Rollin H. Baker, UTEP 4907-08. Record fills in geographic hiatus between specimens from southern Nayarit and adjacent Jalisco (Puerto Vallarta area) and central Michoacán (Dixon, J. R., 1964, New Mexico State Univ. Scientif. Bull. 64-1:1-139). Other species observed on this small island included *Iguana iguana, Ctenosaura pectinata,* and *Cnemidophorus lineatissimus;* many skulls and skeletal elements of sea turtles (seemingly mostly *Lepidochelys*) littered the restricted sandy beach of disembarkation. On this date brown boobies *(Sula leucogaster)* nested on the brim of a rocky precipice where the birds are said to chase ctenosaurs away from their basking sites at the beginning of the nesting season.

SCELOPORUS HETEROLEPIS SHANNONORUM. Nayarit, ca. 1 km S and 27 km E Huajicori, 3 December 1970, UTEP 7413-15. First state record, extending range of subspecies some 70-75 km SE into northern Nayarit from localities near El Palmito, Sinaloa and Revolcaderos, Durango (Webb, R. G., 1969, Herpetologica 25:300-307).

SCELOPORUS MERRIAMI (Canyon Lizard). DURANGO: Sierra de la Campana, 7 km NW La Campana, 30 June 1973, UTEP 4276-79; 4 km NW La Campana, 26 June 1980, UTEP 6052-56. First state record and extends range ca. 75 km WSW of nearest locality in Coahuila (Olson, R. E., 1979, Cat. Amer. Amph. Rept. 227 [map]); specimens not readily identifiable to subspecies.

SCELOPORUS MUCRONATUS MUCRONATUS. HIDALGO: ca. 10 road km (Hwy 45) W Huichapan (17.5 km E Hidalgo-Queretaro state line), 31 July 1979, R. G. Webb and Jerry D. Johnson, UTEP 4580-81. Extends range of subspecies NNW ca. 55 km from nearest locality at Jilotepec, México (Alvarez, T. and P. Huerta, 1973, An. Esc. Nac. Cienc. Biol. Méx. 20:177-184). The two young individuals were taken with the more frequently observed *Sceloporus torquatus* (UTEP 4582-88).

CNEMIDOPHORUS DEPPEI INFERNALIS. JALISCO: 1 km E Atenquique, 12 June 1964, UTEP 5398-99. First state record and extends range some 80 km W of nearest localities in vicinity of Apatzingán, Michoacán (Duellman, W. E. and Wellman, J., 1960, Misc. Publ. Mus. Zool. Univ. Michigan, 111:1-81).

LEPTOTYPHLOPS HUMILIS SEGREGUS (Trans-Pecos Blind Snake). COAHUILA: San José del Aguaje (north side Río Aguanaval, the Coahuila-Durango state line), ca. 21 km NW San Juan de Guadalupe, Durango, 16 July 1975, UTEP 5212. Extends range of subspecies ca. 155 km SE of nearest record south of Tlahualilo, Durango (Williams, K. L., P. S. Chrapliwy, and H. M. Smith, 1961, Nat. Hist. Misc. 177:1-8; Hahn, D. E., 1979, Cat. Amer. Amph. Rept. 232 [map]). Specimen drowned at edge of large flooded area with breeding *Bufo cognatus* (UTEP 5210-11).

MASTICOPHIS BILINEATUS BILINEATUS (Sonoran Whipsnake). AGUASCALIENTES: 2 road km (Hwy 70, DOR) W Calvillo, 31 July 1969, UTEP 7747. On the occurrence of cooter turtles (subgenus *Pseudemys*) in the upper Ohio River Valley

Well documented disjunct colonies of the Ouachita map turtle, *Graptemys pseudogeographica ouachitensis,* and the red-eared slider, *Pseudemys scripta elegans,* in the upper Ohio River system represent probable remnants of preglacial turtle invasions from the Mississippi Valley through the old Teays River (Richmond, 1953; Conant *et al.,* 1964; Thornburg, 1965; Adler, 1968; Seidel and Green, 1981). The relatively recent origin (Kansan) of the middle Ohio River Valley could explain the absence of these species from that portion of the river. Extant cooters of the *P. concinna-floridana* turtle complex have been reported to range from the Mississippi up the Ohio River only as far as western Kentucky and southwestern Indiana (Fig. 1; Minton, 1972; Conant, 1975). The first evidence that these turtles once occurred in the upper Ohio Valley was published by Guilday and Tanner (1965). They reported on a collection of carapace and plastron bones (CM 44459) which were identified by Neil Richmond as *P. floridana.* These bones, estimated to be 1,000 years old (Adler, 1968), were collected from a midden at Mount Carbon, an

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

A Special Publication on the Occasion of the Society's Silver Anniversary

TURTLES OF VENEZUELA

by Peter C. H. Pritchard and Pedro Trebbau

watercolors by Giorgio Voltolina

(about 350 pages, 8-1/2 by 11 inches, 34 maps and 48 full-page color plates)

•

THE BOOK. This outstanding new book will be the first in-depth treatment of a major South American turtle fauna. It covers all turtles known from Venezuela including the mata mata and other side-necks (11 species), tortoises, pond and land turtles (6 species) and the sea turtles (5 species), together comprising fully half of the turtle species described from the South American continent and all species recorded from Trinidad, Guyana, Surinam and French Guiana. The monograph is based on a study of existing museum specimens, an in-depth review of the relevant literature and, most important, the results of intensive field study by both authors in all parts of Venezuela. They made many original observations and discovered two new forms, described here for the first time. Following a discussion of the zoogeography of South American turtles there is an illustrated key to species (in both English and Spanish). Each species account consists of a synonymy followed by a diagnosis; a detailed description (including shell, soft parts, color and sexual dimorphism); and sections on size and growth; distribution and geographic variation; habitat; feeding; reproduction; economic importance; vernacular names; and additional notes where appropriate. There is also a comprehensive bibliography and list of locality records.

The book is beautifully illustrated. There are 48 full-page plates in color, 26 of which are original watercolors and the remainder a collection of 160 photographs of both turtles and their habitats. Samples of both are reproduced on the following pages. In addition, there are two distribution maps for each species: a spot map showing the detailed Venezuelan distribution and a map showing the continent-wide range.

THE AUTHORS. Peter C. H. Pritchard, an Englishman trained at Belfast and Oxford and later, as a student of Archie Carr, at the University of Florida, is currently Vice-President for Science and Research of the Florida Audubon Society. He is one of the world's leading authorities on turtles and is particularly well known for his two previous books, *Living Turtles of the World* (1967) and *Encyclopedia of Turtles* (1979), and over 75 scientific papers, many of them on the ecology and conservation of sea turtles. Dr. Pritchard is intimately involved in conservation, having served the World Wildlife Fund as Executive Officer for its Marine Turtle Specialist Group from 1969 to 1973. For his research he has travelled world-wide, with major field programs in Mexico, the Galapagos Islands, Central and South America, the West Indies, Papua New Guinea and Micronesia.

Pedro Trebbau is now Director of the Caricuao Zoological Park in Venezuela. Trained in Germany as a veterinarian, his work has been largely in zoo administration and he is well known in Venezuela for his natural history television programs. His research and conservation activities have dealt largely with mammals, but he is known to herpetologists for his films on Orinoco turtles and his taxonomic work, with Janis Roze, on coral snakes.

THE ARTIST. Giorgio Voltolina, an Italian, was trained at the Liceo Artistico in Venice and, after emigrating to Venezuela in 1955, worked as artist and taxidermist for several natural history and academic institutions. His illustrations have appeared regularly in scientific publications and in high school and university textbooks, and include all vertebrate groups. Voltolina's drawing of the jaguar, giant armadillo and cock-of-the-rock were chosen for reproduction in a series of gold and silver medals commissioned by the World Wildlife Fund. His magnificent and lifelike watercolors of Venezuelan turtles will, we believe, set a new standard for comparison.

PRICES. Following the sample plates.

ORDERING INSTRUCTIONS

Two editions will be published in early summer 1983. The format is quarto (8-1/2 by 11 inches or 21.5 by 28 cm). Color illustrations are reproduced by a leading printer of faithful facsimiles and of art subjects demanding the very best in color reproduction.

REGULAR EDITION (ISBN 0-916984-11-7), clothbound with gold stamps ..... price, $45
PATRON'S EDITION (ISBN 0-916984-12-5), two leatherbound volumes in slipcase (described below) .. price, $300

The deluxe patron's edition, for the collector and connoisseur, is *strictly limited to 300 copies*, of which 250 are for sale.

- Patron's copies will be exquisitely handbound using the finest imported materials, including red morocco leather spines with raised bands, genuine hand-marbled covers with vellum tips, 24-karat gold top edges, headbands and gold ornamentation.
- Patrons will receive a separate set of the 25 watercolor plates, individually printed on a heavy acid-free stock suitable for framing. These are held as loose sheets in a portfolio bound in leather to match the book. Both volumes will be placed in a custom-made protective slipcase (see photograph).
- Each patron's copy will be signed by the authors and individually numbered. Patron's copies will be reserved on a first-come, first-served basis.

TO ORDER. Orders may be placed with your own bookseller or directly with the Society by writing Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. A price-list of other books, pamphlets and journals published by the Society together with information on membership can be obtained from Dr. Taylor.

The Society publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Contributions to Herpetology* and *Catalogue of American Amphibians and Reptiles*. Currently, dues for individuals are $15 for students, $18 for regular members plus a $5 postal surcharge for members outside the United States.

SPECIAL PRICES TO SSAR MEMBERS

Society members can obtain substantial discounts by placing their orders directly with the Society. These should be sent to Dr. Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. Please make checks payable to "SSAR". Payments must be in U.S. funds. Receipts sent on request only.

Individual members of the Society may purchase copies at the following reduced rates providing that *orders are received by 15 April 1983*. Afterward, prices will revert to the regular rates advertised above. Please mark the edition you desire and return this order form with payment to Dr. Taylor. *All prices include surface postage, world-wide.*

- ☐ **Regular edition,** clothbound ... price, $35
- ☐ **Patron's edition,** leatherbound .. price, $250

If you request a patron's edition, a deposit of $75 is required with order.

Please *print* below the address to which your copy should be mailed:

archeological site near Boomer, Fayette County, West Virginia. This locality is in the old Teays River Valley below Kanawha Falls (Fig. 1).

Adler (1968) re-identified the Mount Carbon bones as *P. scripta*. His decision was based primarily on the presence of longitudinal ridges on the first pair of peripheral bones. Longitudinal carapace ridges, however, are also characteristic of other *Pseudemys* species (Carr, 1952). Examination of two shells of *P. concinna-floridana* from southern Indiana (UMMZ 128176 and 133845) shows strong longitudinal ridges on the posterior margins of the first peripheral bones. An examination of the ventral surface of the nuchal bone from the Mount Carbon specimen (Adler, 1968, illustrates dorsal surface only) indicates an area of nuchal (= cervical) scute underlap which is broader than long, typical of *P. concinna* and *P. floridana* (Weaver and Rose, 1967). For comparison, nuchal scute underlap of six adult *P. scripta* from the Kanawha and Little Kanawha Rivers, West Virginia (WVBS 3763, 3764, 3964, 4453, 4454 and MES 862) was analyzed and all were found to have nuchal scutes which are ventrally longer than broad. Although the nuchal bone from the Mount Carbon site is not entire, it was possible to accurately estimate total length. This allowed calculation of nuchal scute underlap according to the method of Weaver and Rose (1967). A value of 21.7 was obtained, which places the specimen at the upper range limit of *P. floridana* and well below the lower limit (26.0) for *P. scripta* (Weaver and Rose, 1967). Therefore, evidence for the probable occurrence of cooters in the upper Ohio River System is resurrected. A questionable record based on a skull from Franklin County, Ohio (Fig. 1) is worthy of mention. This specimen (MCZ 57019), examined by the authors, is from a juvenile and accompanied by the following data: *Pseudemys floridana hieroglyphica;* collector, K. Barnobey; 1956; Big Walnut Creek, Rt 33, Columbus, Ohio. Difficult to determine on such a small cranium, there is evidence of a denticle at the anterior end of the middle ridge of the upper triturating (alveolar) surface, a distinguishing characteristic of *P. concinna-floridana* (McDowell, 1964). Although the collection locality is near the old Teays Valley, it is above the terminal moraine. It is quite possible this specimen was a released pet.

Two recent turtle specimens collected in Mason County, West Virginia, 91-106 Km downstream from the Mount Carbon site, near the junction of the Kanawha and Ohio Rivers (Fig. 1), provide additional support for the presence of *P. concinna-floridana* in the upper Ohio (Teays) Valley. An adult male (WVBS 3965, carapace length 248 mm) collected alive by Larry Sawyers, May 1969, at the mouth of Nine Mile Creek (a small Kanawha River tributary) has the following characteristics typical of cooters (Ernst and Barbour, 1972): cutting edge (tomium) of upper jaw rounded without a notch, ridges of the alveolar surfaces strongly tuberculate (dentate), nuchal scute underlap short, anterior plastral seams with a dark pattern, very weakly keeled carapace with light-colored linear reticulate markings on laminae, head and neck stripes narrow with no evidence of a wide postorbital stripe or blotch. A second Mason County specimen (WVBS 3155), formerly identified as *Graptemys geographica* (Green, 1969), also fits the above description and is referrable to *P. concinna-floridana*. This turtle is a large female (carapace length 325 mm) collected by Leo Calandros, July 1963, in the Ohio River near Point Pleasant. Recent efforts to collect cooters and map turtles in Mason County, utilizing trammel nets and bait traps, have failed. However, absence of suitable basking sites and heavy siltation in the rivers due to dredging activities, in addition to the shy behavior, preference for deep water, and herbivorous food habits of cooters, make collecting very difficult. A third specimen of *P. concinna-floridana* was recently (June 1981) collected by Bryant Williamson 1.0 Km E of Ona, near the Mud River (a Guyandot-Ohio River tributary), Cabell County, West Virginia. This turtle (MES 870, carapace length 238 mm) is an adult male and has markings similar to the Mason County specimens. The locality is also in the old Teays Valley, 30 and 46 Km SW and S of the Mason County sites (Fig. 1).

The three recent specimens from Mason and Cabell Counties and archeological material from Fayette County appear to partially bridge a large gap in the range between the southern Indiana population and an isolated aberrant colony of cooters from the New River (a majority tributary of the upper Kanawha River), Bluestone Reservoir (Fig. 1), Summers County, West Virginia (Bayless, 1972). However, New River *Pseudemys* show little resemblance to the Mason and Cabell County turtles. Examination of 12 adults from Bluestone Reservoir (USNM 192635-7; WVBS 4093, MES 489, 526, 528-9, and four uncataloged) show all having weak cusps on the upper jaw, broad head and neck stripes especially ventrally, and low carapaces. The ratio of shell height to carapace length of five females ranges 0.326-0.394 compared to 0.440 for the Mason County female. Seven adult males range 0.311-0.346 compared to 0.367 and 0.357 for the Mason and Cabell County males respectively. The only entire adult specimen of *P. concinna-floridana* from Indiana available for comparison (UMMZ 101754, male) strongly resembles Mason and Cabell specimens, having a deep shell (0.362), uncusped upper jaw, and narrow head and neck stripes.

We conclude that the natural occurrence of cooters in the upper Ohio Valley of West Virginia is likely. Severe disturbance of the mainstream habitats in this area may be responsible for near extirpation of these turtles which are apparently relicts of a pre-Kansan Teays River dispersal from the Mississippi Valley. Mason and Cabell County cooters are probably conspecific with *Pseudemys* in the New River of West Virginia, but do not appear closely allied to that colony. Although both populations occur in the same drainage system, they are separated by Kanawha Falls, believed to be one of the largest natural river barriers east of the Rocky Mountains (Jenkins *et al.*, 1971). The geographical origin and taxonomy of *Pseudemys* in the New River were investigated by Seidel (1981).

ACKNOWLEDGMENTS

We are grateful to Jack McCoy (Carnegie Museum), Arnold Kluge (University of Michigan Museum of Zoology), Ernest Williams (Museum of Comparative Zoology), George Zug (United States National Museum), William Palmer (North Carolina State Museum of Natural History) and Larry Bayless (Concord College) for loan of specimens. Stan Mills, Jim Gould, Sam Reynolds, Larry Bayless, Mike Little, Allen Brant and Greg Molter helped with the collection of specimens. We thank Mike Little and Dan Evans for com-

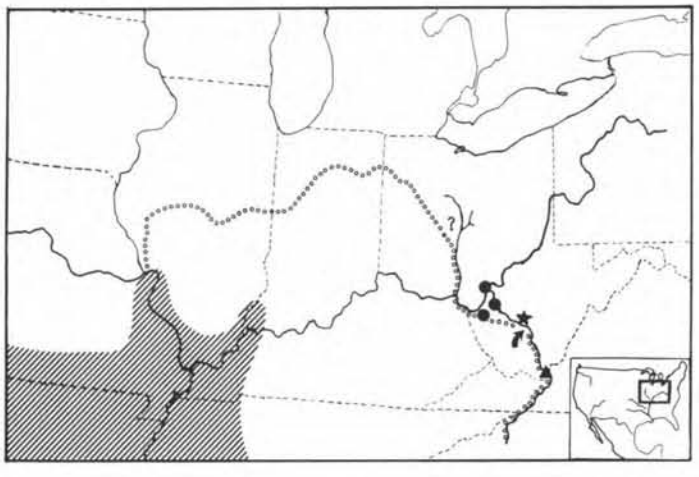

Figure 1. Distribution of cooter turtles in the Ohio and upper Mississippi River drainages. Closed circles are locality records for Mason and Cabell Counties, West Virginia. Star indicates the Mount Carbon archeological site. Triangle represents the population in the New River at Bluestone Reservoir. A questionable record for Franklin County, Ohio is indicated. The course of the old Teays River is represented by small open circles and the location of Kanawha Falls is indicated by an arrow.

BOOK REVIEW

Amphibians of Argentina, by J. M. Cei, Monitore Zoologico Italiano, Italian Journal of Zoology, (N.S.) Monogr. 2, 1980 (Via Romana, 17-50125, Firenze, Italia), xii+609 pp., 214 figs., 16 pls., 24 color pls., price for Italy and abroad Lit. 56.000 (for M.Z.I. subscribers Lit. 50.000).

This long-awaited monographic treatise of Argentine amphibians is a product of some 30 years of first-hand experience by Jose Miguel Cei, one of the leading authorities on the South American herpetofauna. The author, formerly professor of general biology at the Universidad Nacional of Tucuman, and since 1958 Director of the Instituto de Biologia Animal at the Universidad Nacional de Cuyo, Mendoza, Argentina, now resides at Rancho Somuncura, Rua Fausto de Fiqueiredo, Birre, 2750 Cascais, Portugal.

Cei's book (text in English) is the most comprehensive contribution on amphibians that has appeared for any South American country, and contains just about everything that one would expect in such a book. The subject matter is parceled into three sections. The introductory section (51 pp.) treats various topics as they apply to all Argentine amphibians — an historical review, remarks on general classification, morphological characters, ecophysiological trends, sex cycles and reproduction, behavior, biochemical-immunological relationships, karyotypes, and zoogeography. There follows 16 plates (each of two photographs) that depict various habitats for amphibians. The second section (49 pp.) is devoted to keys to identification (in both English and Spanish), which treat genera and species of caecilians, and superfamilies, families, genera, and species and subspecies of frogs and toads. The third and most lengthy section (353 pp.), followed by 24 plates of colored paintings (each depicting varying numbers of taxa), is the account of the 138 species and subspecies (2 caecilians, 2 microhylids, 23 bufonids, the monotypic rhinodermatid, 5 ceratophryids, 70 leptodactylids, 4 pseudids, 30 hylids, and 1 centrolenid), with the largest genera being *Hyla* (21), *Telmatobius* (18), *Bufo* (15), and *Leptodactylus* (14). No new taxa are described. The standard format for discussion of taxa includes a diagnosis for each genus, and diagnosis, description, distribution, life history, and tadpole for each species and subspecies (with subsections on Remarks interspersed). The synonymies for each species and subspecies include in chronological order all different name-combinations (type-localities accompany original descriptions and nominal synonyms), with the most important subsequent usages of that same name listed under each synonymic entry. All taxa can be readily found in the text by referring to the paginated Contents (v-xii pp.). Numerous illustrations (line-drawings and photographs; most original by the author, some previously published) are scattered through the accounts of species and aid in identification. The illustrations include primarily entire animals, aspects of heads, hands, feet, pectoral girdles, some skulls, and tadpoles, and also the type-specimens of *Paludicola illotus* Barbour (= *Alsodes nodosus*) and of *Alsodes gargola neuquensis* Cei. There are also 14 interspersed distribution maps, each of southern South America, that show only generalized geographic ranges of taxa in Argentina; lists of specimens examined (or literature records) are lacking, although some specimens are documented by museum numbers and localities in legends of illustrations. Twelve appendices (10 pp.) provide data relevant to Argentine amphibians that were received by the author after this monograph was in press (manuscript received 4 July 1976, published 30 June 1980). A summary (in English and Spanish, 7 pp.) is followed by a list of 593 references (28 pp.) that includes some papers not cited in the text (as noted by author) and generally excludes references mentioned in the synonymies. In the terminal, double-columned index (13 pp.) page numbers in italics indicate illustrations and in boldface type the main accounts for quick reference.

Technically, this work has good quality illustrations, and is relatively free of typos. The book is paper-bound (journal cover format of Italian Journal of Zoology) with the text on good quality glossy paper, is about 38 mm thick, and is covered by a loose, glossy-paper, protective jacket; continued use will soon necessitate cloth-binding. The publisher deserves credit for a good job of editing, printing, and producing a volume of pleasing format. The relatively high price of Lit. 56.000 is perhaps not unreasonable considering the bulk and the inclusion of 24 colored plates and one colored photograph.

Making no pretense of an intimate knowledge of the Argentine amphibians, I have necessarily refrained from commenting on the systematics of the taxa involved. My only complaint is a preference for spot localities on the distribution maps. The author is to be congratulated. His comprehensive, synthetic treatment of a large geographic segment of the amphibian fauna will be ranked among the outstanding contributions to the study of the South American herpetofauna. Amphibians of Argentina is recommended without reservation.

1982 SSAR GRANTS-IN-HERPETOLOGY AWARDS

The Society for the Study of Amphibians and Reptiles is pleased to announce the following awards in the 1982 Grants-In-Herpetology Program:

GRADUATE STUDENT RESEARCH:

David M. Hillis, Museum of Natural History, The University of Kansas, Lawrence. "A Quantitative Analysis of Hybrid Dysgenesis Among Members of the *Rana pipiens* Complex." $400.

HERPETOLOGICAL CONSERVATION:

Debra Dick, Department of Biological Sciences, Florida International University, Miami, Florida. "A Non-Fatal Immunological Technique for Sexing Sea Turtles." $370.

HERPETOLOGICAL RESEARCH IN ZOOS:

Susan M. Barnard, Department of Herpetology, Atlanta Zoological Park. "Diagnostic Atlas of Reptile Intestinal Parasites." $300.

Richard Hudson, Fort Worth Zoo, and Bonnie Raphael, Dallas Zoo. "A Limited Antibiotic Study in Turtles." $100.

REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS:

John Cebula, 345 W. Ethel Avenue, Lombard, IL. "The Herpetology of DuPage County, Illinois." $250.

Bob Belmore, Hope High School, Providence, Rhode Island. "The Status and Distribution of the Bog Turtle, *Clemmys muhlenbergi*, in Massachusetts." $150.

SSAR extends its congratulations to all recipients of awards and encourages the submission of proposals for next year's program. SSAR also expresses its thanks to the 1982 Grants-In-Herpetology Committee, composed of: Martin J. Rosenberg (Chairperson), Terry E. Graham (Conservation Research), John B. Iverson (Regional Herpetological Society Projects), Linda Maxson (Graduate Student Research), and Lyndon A. Mitchell (Herpetological Research in Zoos). ●

AUTHORS SOLICITED FOR SALIENTA ACCOUNTS IN *CAAR*

A number of species in the anuran fauna of the United States have had no authors assigned, or the assignments have been relinquished by their prospective authors. If you would care to volunteer to write the *Catalogue* account for one or more of the species listed below, please contact the undersigned. Accounts available are: *Bufo americanus, B. boreas, B. cognatus, B. debilis, B. exsul, B. microscaphus, B. punctatus; Hyla chrysoscelis, H. cinerea, H. crucifer, H. eximia, H. regilla, H. versicolor; Hypopachus variolosus; Pseudacris clarki, P. nigrita; Rana berlandieri, R. catesbeiana, R. onca, R. pipiens, R. utricularia (sphenocephala); Syrrhophus cystignathoides, S. guttilatus, S. marnocki.* A number of accounts on the generic level are open, too. Richard G. Zweifel, Salientia Editor, Catalogue of American Amphibians and Reptiles, Department of Herpetology, American Museum of Natural History, New York, NY 10024. ●

STRIPED PATTERN MORPHISM IN THE PRAIRIE KINGSNAKE, *Lampropeltis c. calligaster*

INTRODUCTION

Dorsal striping in normally blotched snakes has been noted for several species. Klauber (1936, 1939) described striped *Lampropeltis getulus* and Riemer (1958) studied *Pituophis melanoleucas.* Tryon (1979) described a partially striped *Lampropeltis mexicana blairi* and Williams (1978) and Gehlbach (1962) mentioned partially striped specimens of *Lampropeltis triangulum.*

Contrary to Ashton (1973) several instances of striping in *Lampropeltis calligaster calligaster* are mentioned in the literature. Blanchard (1921), Schmidt and Davis (1941) and Wright and Wright (1957) described ontogenetic pattern modification in the prairie kingsnake wherein older individuals may have faint longitudinal stripes in addition to the usual blotches. Miller (1902) mentioned a similar occurrence in *L. c. rhombomaculata.* Minton (1972), Smith (1961), Anderson (1965) and Cox (1972) discussed dorsal striping in prairie kingsnakes.

Specimens of *L. c. calligaster* mentioned in the literature were examined (if possible) and compared to several that were previously unreported. Prairie kingsnakes were obtained from the United States National Museum (USNM), Chicago Academy of Sciences (CA), Eastern Illinois University, Charleston and the University of Kansas Museum of Natural History (KU).

RESULTS AND DISCUSSION

Striped prairie kingsnakes have been collected from throughout the northern portion of its range.

Blanchard (1921) described a *Lampropeltis c. calligaster* from Jersey Co., Illinois which exhibited the striping noted in darkened specimens. This snake (USNM 61726) had faint pattern, but did not possess any pronounced striping. Minton (1972) mentioned three striped specimens from Indiana and Kentucky. Apparently none are extant (pers. com.).

Anderson (1965) described in detail three striped hatchlings from DeKalb Co., Missouri (KU 82198, 82199, 82200). They were hatched in captivity along with nine normal littermates. The mother was also patterned normally. Anderson (1965) also collected a single hatchling in Clay Co., Missouri (KU 84136). All hatchlings had well pronounced, but incomplete striping.

Ashton (1973) described a single striped hatchling (KU 154482) from a clutch of 13 eggs. Two others possessed slight aberrations in pattern and the remaining ten were normal. The female was collected in Osage Co., Oklahoma during June, 1972 and was patterned normally.

Smith (1961) mentioned a striped adult collected near Springfield, Sangamon Co., Illinois (CA 17198). Another adult, collected east of Charleston, Coles Co., Illinois during October, 1966, is uncatalogued in the collection of Eastern Illinois University, Charleston. Both possess two dorsal stripes which start immediately posterior to the parietals and end just anterior to the vent. The stripes pass through an occasional blotch, and laterally a series of small blotches are fused to form an incomplete stripe.

Four prairie kingsnakes were hatched from a clutch of eight eggs laid by a normal female collected in St. Clair, Co., Illinois (Cox, 1972). Two had prominent dorsal stripes and two were normal. Two hatchlings, one striped and one normal, have been lost. The remaining striped specimen has many fragmented ventrals, while its littermate is normal. The striped specimen is being maintained alive for further study.

Of the specimens examined, those with prominent dorsal stripes are patterned similarly. The stripes are approximately two to four scales wide and are located one to two scales on either side of the mid-dorsal line. With one exception, scutellation is normal.

Vinegar (1974) described pattern modification as a function of incubation temperature in *Python molurus* and also noted gross abnormalities in scutellation and morphology. Bechtel and Bechtel (1978) discussed the inheritance of dorsal striping in *Elaphe g. guttata* and indicated that the striping was probably due to recessive alleles. Either mode is a possible cause for the striping in *Lampropeltis c. calligaster.* The consistency of the pattern changes implies a genetic relationship.

ACKNOWLEDGMENTS

I wish to thank Bruce Bury, Stephen Busack, George Iannarone, Ed Moll and Roy McAllister, Jr. for the loan of specimens, and C. J. McCoy and Burt Monroe for inspection of their respective collections. Also thanks are due to Richard S. Funk and George R. Pisani for critically reviewing the manuscript.

BREEDING OF THE GREEN SEA TURTLE, *Chelonia mydas*, ON THE ISLAS REVILLAGIGEDO, MEXICO

Little is known about the biology of green turtles, *Chelonia mydas*, on the Islas Revillagigedo, Mexico. The islands are located 350 to 650 km south and southwest of Baja California. A few expeditions have stopped at the islands (Richards and Brattstrom, 1959) but little has been reported on the breeding of the sea turtles (Brattstrom, 1955). I have had an opportunity of visiting the four islands in the archepelago on numerous occasions during geological and biological investigations of Bárcena Volcano, 1952, on San Benedicto Island (Brattstrom, 1963; in press). I here report (Table I) on breeding times and numbers of turtles (or the presence of tracks on beaches).

Green sea turtles nest only in one large bay (Sulphur) on Clarion Island, and on two places (Fig. 1) on Socorro Island (Playas Blancas at Cape Henslow on the northwest corner of the island and three beaches in the vicinity of Academy Bay on the northern most portion of the island). The breeding season started in 1978 about mid-April. In 1953 breeding had obviously started earlier (March 18) and in May, 1955 there were tracks on both Clarion and Socorro. Mating has been observed in May and November. This suggests a long breeding and nesting season.

Diurnally, emerging sea turtles have a precarious time getting from nests to the sea. I have discovered young sea turtles in the stomach of the Clarion Island Racer, *Masticophis anthonyi*, and in the pellets of the Clarion Island Burrowing Owl. I have also observed the Socorro Red-tailed Hawk, which normally eats mostly lizards, soaring over the beach at Academy Bay as young turtles were emerging.

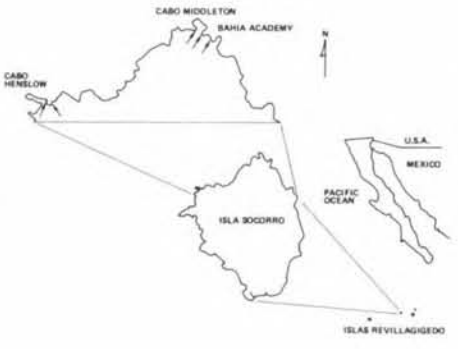

Fig. 1. Map of the Islas Revillagigedo, Mexico, showing the location of beaches where nests and tracks of green turtles were found on Socorro Island.

TABLE I. Reproductive observations for Green Sea Turtles, *Chelonia mydas*, on The Islas Revillagigedo, Mexico.

1953: March 18, Socorro, fresh tracks at Playas Blancas
March 25, Clarion, fresh tracks at Sulphur Bay
November 20, Socorro, fresh tracks and young emerging, Academy Bay.

1955: May 3, Socorro, fresh tracks, at Academy Bay
May 7, Clarion, fresh tracks, Sulphur Bay, pair mating in bay in afternoon.

1971: November 8, 9, Clarion, about 30 old tracks, one fresh track morning of 9th, mating observed in the bay and young emerging, Academy Bay; 18 nests, at least four, less than 3 days old, Playas Blancas.

1977: Socorro, estimates from 1978 observations indicate that there were 23 old nests at Playas Blancas and 47 on the three beaches at Academy Bay. This is probably not a true measure of total breeding at these sites as later females would obliterate earlier nests.

1978: April 11, Socorro, no fresh turtle nests or tracks at Playas Blancas indicating no nesting here yet this year.
April 14, Socorro, seven fresh nests and tracks on three beaches at Academy Bay, all apparently made in last two to three days; no older tracks.

1981: April 5, Socorro, 16 fresh turtle tracks on the three beaches at Academy Bay, 12 tracks about a week old; 96 old (last years) nest sites.
April 7, Socorro, no tracks on the beaches at Playas Blancas, indicating no breeding on this beach yet this year; 32 old nest sites.

COURTSHIP BEHAVIOR OF THE QUEEN SNAKE, *Regina septemvittata*

Studies of courtship and mating behavior of snakes have only recently been conducted carefully enough so that evolutionary aspects of this activity can be examined. In particular, Gillingham has used methods of frame by frame analysis of movie films to make comparative studies of snake reproductive behavior (Gillingham, 1979). His work has been primarily with species exhibiting what Davis (1936) defined as "coluber" type courtship. Several other authors have examined the reproductive patterns of the natricine snakes (Blanchard and Blanchard, 1942; Pisani, 1976; Mushinsky, 1979), but species differences have not been discussed. *Regina* is known to be a quite distinct genus of natricine snake, particularly in several behavioral characteristics, *i.e.* feeding behavior. Its reproductive behavior might therefore also exhibit variation from the typical pattern. This report is the first dealing with courtship activity of any member of *Regina* and examines the mating behavior of the Queen snake, *Regina septemvittata*.

Male and female *Regina septemvittata* were collected in the springs of 1978 and 1979 from southwestern Ohio. Within a few days of capture, these snakes were placed together in a large aquarium (1.5m x ½m) containing a gravel substrate. Courtship behavior of four males was observed and filmed with a super 8 movie camera. The films were then analyzed frame by frame for certain behavioral components of courtship.

In most regards, male queen snakes showed courtship behavior closely paralleling other natricines. The male approached and tongue flicked the female repeatedly. The male mounted the female and proceeded to move forward until aligned on her dorsum. At this time the male queen snakes began a behavior different from other colubrids. They proceeded to "bounce" dorsoventrally on the female. This movement was a vertical oscillation of the first 6 to 20 cm of the neck. It did not involve any lateral sliding of the body but in other regards did appear to be similar to the writhe-bump seen by Gillingham in *Elaphe* (1979). Each bounce lasted 0.05 seconds and the bounce rate alternated between 60 to 70/min. up to 91 to 115/min. The slower rate involved higher dorsoventral movement (1 to 2 cm off the female, Fig. 1). The faster rate occurred with oscillations in which the male did not lose contact with the female's dorsum. After a variable period of this behavior, the males would begin the tail-search copulatory attempts. As the typical natricine caudal-cephalic waves were absent this suggests the vertical oscillations substitute for this reproductive cue.

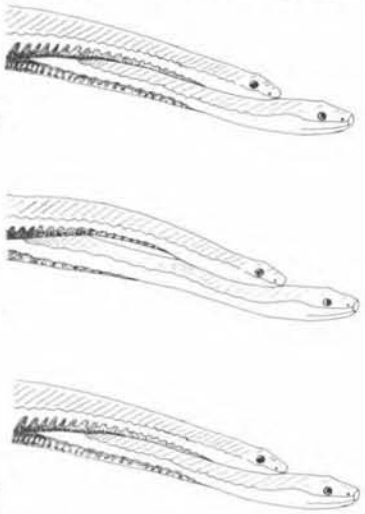

Figure 1. The sequence of movements in a single "bounce" of a male queen snake, *Regina septemvittata*, courting a female.

Male activity while mounted on the female's trunk appears to show more evolutionary variability than do other stages of courtship. Gillingham (1979), for example, compared the variation in caudal-cephalic waves and writhe-bumps in *Elaphe* occurring during this period. *Regina septemvittata's* different tactile behavior also supports this idea. It, therefore, seems likely that these species differences in tactile activity of males while aligned on the female have evolutionary implications. The most logical explanation is that they convey species specific identification designed to bring about female passivity. Examination of the tactile-alignment behavior of both closely related and evolutionarily distinct species should give more insight into this possibility.

ACKNOWLEDGMENTS

I thank George Pisani and James Gillingham for their comments on this manuscript.

PLASTIC BAGS IN THE INTESTINAL TRACTS OF LEATHERBACK MARINE TURTLES

While collecting skeletal material of *Dermochelys coriacea* at a site in coastal Peru where leatherback carcasses were discarded by fishermen, I found evidence of plastic in the intestinal tracts of these specimens to be common. Plastic bags and film were noted in 19 of 140 (13%) specimens examined in November 1980 near Pucusana, Depto. Lima, Peru. The xeric climate of coastal Peru had mummified many carcasses and slowed biological decomposition of tissues. Although all specimens examined had been butchered some considerable time before discovery (perhaps more than 14 months earlier), the intestines had been left in the carapaces and had dried *in situ*. No attempt was made to open or examine the entire digestive tract due to the dried, rotted, and often incomplete nature of the viscera. Consequently, all cases where plastic was noted involved sizable pieces of plastic which protruded or were exposed from the intestine. In all cases the plastic was noted to be within the lumen of the digestive tract and in a twisted, elongate form suggesting peristalic transport. Because of the limiting conditions under which observations were made, the actual occurrence of plastic in *Dermochelys* is probably much higher than recorded.

Hays and Brown (1981) found plastic bags in 9 of 39 (23%) specimens of *Chelonia mydas* captured near Pisco, Depto. Ica, Peru. Coastal Peru is an area of low human population density. Consequently, the high incidence of plastic bags in the intestinal tracts of marine turtles is noteworthy.

Brongersma (1969; 1972) recorded plastic materials in the intestinal tracts of two leatherbacks from European waters. Carr (in Cornelius, 1975) attributed a mass mortality of *Chelonia* in Costa Rica to the ingestion of plastic bags. Pritchard (1971) mentioned that plastic is found in leatherback intestines. Carr and Pritchard did not detail their observations. Mrosovsky (1981) recently reviewed data from 16 leatherback turtles, 7 of which (44%) contained plastic. He also noted that 7 of 8 leatherbacks studied in France by Duron and Duron (1980) had swallowed plastic. The information on plastic bags in *Chelonia* and *Dermochelys* in Peru is important in confirming the incidence in a specified number of animals. Frazier (1980) noted that plastics are indigestible and they may impact the gut. The green turtles studied by Hays and Brown (in press) and the leatherbacks described herein were butchered animals which presumably were captured alive. Therefore the plastics found had not yet caused death. Thus, the incidence of turtles dying because of plastics is unknown. The possibility of death or malnutrition resulting from plastic bag impaction of the gut should be carefully considered and investigated in dead or distressed animals from other sources. Marine turtles actively feed on jellyfish, and plastic bags floating in water potentially resemble jellyfish in color,

form, and texture. Therefore, it is possible that plastics are consumed whenever encountered by foraging marine turtles. Since plastic film products are used and disposed of worldwide, the potential for effecting marine organisms, including turtles, is great.

TECHNIQUES

A TIME-EFFICIENT, LOW COST METHOD FOR THE LABORATORY REARING OF FROGS.

INTRODUCTION

There has long been a need for a reliable method whereby laboratory populations of anurans could be both maintained and perpetuated at modest cost and with minimal time expenditure. The availability of reliable methods for the raising and maintenance of anurans in a time-efficient operation and at modest cost is important to biologists in many disciplines. However, small scale frog rearing operations are not common because of several fundamental problems. These include: design inadequacies of many commercially available rearing tanks; lack of an adequate food supply for transformed frogs; labor intensive service operations; high operating costs; and contagious diseases. Large scale operations (Nace, 1968) generally are not practical for use by individual research laboratories because they demand a considerable investment of time and/or are prohibitively expensive.

During the past several years, I have reared modest numbers of frogs through one or more generations. A review of the literature on frog culture techniques (e.g., List, 1957; Culley, 1976) has proven to be helpful, as have been the personal accounts of colleagues. The following report describes a generalized procedure for frog rearing that incorporates both the products of my own efforts of the past several years, as well as information obtained from other sources (G. Nace and C. Richards, pers. comm.). In this system, traditional problems associated with food supply and diet, containment and disease, serviceability, and cost are minimized by emphasizing simplicity without sacrificing animal welfare considerations. By utilizing the basic procedure and materials described herein, it is possible to rear hundreds of adult frogs annually from eggs at a modest cost and with a minimal time expenditure. In the present study, leopard frogs (*Rana pipiens, R. blairi, R. sphenocephala, R. berlandieri, R. magnaocularis, R. chiricahuensis, R. forreri,* and the lowland form of Platz and Platz, 1973) as well as *Hyla chrysoscelis, Bufo woodhousii, Bombina orientalis,* and *Pachymedusa dacnicolor* were used. With minor modifications the basic system should be suitable for many other anuran species.

METHODS AND MATERIALS

The method relies on three major components. The construction, preparation, and operation of each component are described below. Included with the description of each component is a section detailing costs.

I. Cricket colony

Rearing boxes. — An individual cricket rearing box is shown in Figure 1. Basically, the box is constructed from a single 4 X 8 ft sheet of one half inch plywood and miscellaneous hardware. The box incorporates a light bulb heat source, ventilation holes, an escape barrier, and a hinged access lid with an inspection window. The individual components and specifications required to construct the basic box are provided in Fig. 1.

Figure 1.

Rearing procedure. — Crickets *(Acheta domestica)* thrive under the appropriate temperature and humidity conditions when provided with adequate water and food. Commercial pelletized rabbit feeds provide an excellent food source for crickets of all ages. Alternatively, chicken mash can be used, but it is subject to mold. A 100 watt incandescent light bulb will maintain an inner box temperature of about 32-40° C when the box is placed in a room at 20-25° C. In a cooler room, a bulb or higher wattage or multiple bulbs can be used to bring the internal box temperature to about 32-40° C. Alternatively, the entire box can be placed in a high temperature room. An escape barrier is necessary to prevent the crickets from reaching the lid area of the box. Construction of the foil barrier is explained in Figure 1. The cricket life cycle lasts about eight to 10 weeks and is temperature-dependent. Therefore, the colony should be started several weeks prior to the anticipated need for crickets. The colony can be operated efficiently using just three cricket boxes. To start the colony, 1,000 adult crickets can be obtained from a commercial supplier (*e.g.,* Fluker's Cricket Farm, Inc., 2625 Beech Street, Baton Rouge, LA 70805). On arrival, the crickets and packing material should be carefully emptied into a rearing box. Spread one cup of feed on the floor of the box. As an alternative, the food can be placed on a paper plate. Use a plastic poultry waterer (available at farm supply stores) as a source of water for the crickets. The waterer should be fitted with a sponge "rubber" insert to prevent the crickets from drowning. Figure 2 illustrates the design of the insert. Fill a greenhouse seedling tray (plastic) or similar container (measuring about 30 X 30 X 7 cm deep) with damp peat moss and place the tray against the wall in a corner of the box near the light bulb. The adult female crickets will promptly begin to deposit eggs beneath the surface of the moss. Do not permit the surface of the moss to dry out and do not add water to the point of saturation. Keep the tray in the box for about 48 hours in order to acquire several thousand eggs. Cricket eggs are white, cylindrical structures about three to four millimeters in length. Next, place the egg tray in a second cricket box (beneath light bulb) and cover lightly with a sheet of newspaper. Do not allow paper or other flammable materials within several centimeters of the light bulb. Check the eggs daily and add water if neces-

CHARLES W. GILMORE'S

FOSSIL LIZARDS OF NORTH AMERICA

In honor of the 50th Anniversay in 1978 of the first edition of Charles W. Gilmore's FOSSIL LIZARDS OF NORTH AMERICA, the Riverside Museum Press made this classic monograph available again to the scientific community. Originally published by the National Academy of Sciences in 1928 as Scientific Memoir 22, it stands as one of the most important works in the area of systematic paleoherpetology and serves as a valuable reference for both the herpetologist and the paleontologist.

This monograph covers all North American lizard families and gives complete oesteological accounts of the various genera and species (exclusive of Mosasauridae) up to 1928. This new edition provides an introduction by Dr. Richard D. Estes summarizing the advances in paleoherpetology during the past 50 years. FOSSIL LIZARDS OF NORTH AMERICA is reprinted in its original size with all plates and figures illustrated as in the original. This reprint comes in a handsome hardcover to insure many years of utility.

PRICE: $24.95 plus $2.00 shipping & handling (Calif. residents add 6% sales tax).
INSTITUTIONAL DISCOUNT: 10% off ($22.45 + $2.00 shipping & handling)for Museums, Libraries, and Schools.
BOOKSELLERS DISCOUNT: 10 or more copies - 40% off ($14.97 ea. + shipping costs).
NOTE: Please include your sales permit number with your order. Billing terms: Payment with order or within 30 days of receipt of books.
FOREIGN ORDERS: Payment must be in U.S. funds and include sufficient ammount for overseas shipment.
SEND ORDERS TO: RIVERSIDE MUSEUM PRESS, 3720 Orange St., Riverside, CA, 92501

sary to prevent desiccation. The eggs will hatch in about nine to 12 days. Alternatively, a drying oven (vents closed) or heated room (chamber) at about 35-38 C can be used to incubate the eggs. When the newly hatched crickets begin to emerge, provide them with several slices of fresh potato placed on the surface of the moss and on the floor of the box near the tray. Newly hatched crickets appear to prefer the potato slices to pulverized chow. Cover with a single sheet of newspaper. Newly hatched crickets often will drown in the sponge rubber waterer, so wait about 10 days before placing a waterer in the box. In the meantime, keep the peat moss damp as it will serve as a source of moisture for the young crickets. Supplement the potato slices with pulverized rabbit chow (use a blender to disaggregate the chow). Sprinkle 50-100 grams of the pulverized chow on the floor of the box and on the newspaper covering the tray each day for two weeks. After about 10 days, most of the young crickets will be large enough to use a waterer. Discard the egg tray contents at this time and position the waterer against the side of the box to facilitate access to the crickets. The sides of the plastic waterer should be rough-sanded in order to increase traction for the small crickets. The surface area of the box (important in determining the carrying capacity of the system) can be increased substantially and hiding places can be created by placing packing dividers (*i.e.*, cardboard partitions commonly used to provide separation in shipping cartons of small bottles, *etc.*) on the floor of the box near the lighted (warmest) end. Rusted metal cans are also useful as they provide hiding places as well as a convenient means to handle the crickets. Cover with a sheet of newspaper.

About 10-14 days after the eggs hatch, start to shift the feed from pulverized rabbit chow to the intact pellet form. Place a small quantity of pellets on a paper plate or directly on the box floor. The correct amount of pellets to be used depends on both the number and size of the crickets in the box. Generally, 200-400 cubic centimeters (whole pellet volume) per box per day is adequate. If the quantity provided is not consumed in about 24 hours, decrease feeding and vice versa. From this point onward, the box must be kept reasonably free of dead crickets, feces, and any decaying chow. Lift the cardboard material and use a metal-edged dust pan or similar device to scrape waste material into a pile at one end of the box. The crickets will disperse from their hiding places when disturbed, so the scraping and discarding operation should be performed on alternate days. That is, on one day, scrape waste material to the unlighted end of the box. On day two, discard the waste pile of the previous day first and then scrape the floor as was done on the previous day, *etcetera.* This approach reduces the loss of large numbers of crickets. A surgical mask (or similar air filtering apparatus) should be worn as some individuals are allergic to the dust created during the cleaning operation (C. Richards, pers. comm.).

About four weeks after receiving the original shipment of starter crickets, an identical second order of crickets should be placed in the third rearing box along with a tray for collecting eggs. When sufficient eggs have been obtained, remove any remaining crickets from the first box and add the new tray of eggs. The crickets in the second box will mature about six to seven weeks after hatching. Retain at least 1,000 adults from this group for breeding stock. These will supply the eggs for the next generation (to be started in the third box as those adult crickets are utilized). Mature females will exhibit long ovipositers and males will begin to "call." Be certain that no adult crickets are in a box before adding an egg tray. When the colony has been established, one box should contain eggs or newly hatched crickets, a second box can be expected to contain half-grown individuals, and the third box should contain adults. This general, staggered pattern can be maintained indefinitely and without the purchase of additional crickets. The system will produce about 1,000-4,000 crickets each week. Three rearing boxes are required to maintain a staggered rearing cycle. The use of four or more boxes will increase productivity and moderate any accidental interruption of the rearing cycle.

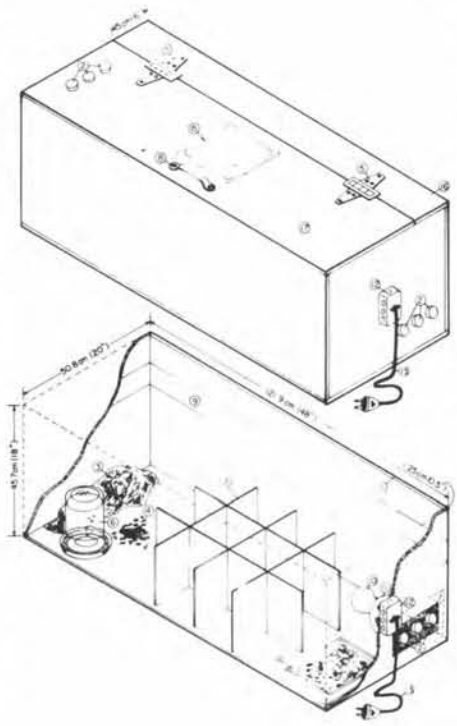

Figure 1. Structural diagram of the cricket rearing box. Components are : 1) ½" plywood (painted inside and outside), 2) number 7 rubber stoppers in 1¼" ventilation holes (covered on inside with wire window screening and bonded to box surface with silicone caulk), 3) waste pile, 4) cricket food (rabbit chow), 5) hinge (4" strap), 6) waterer, 7) cardboard insert, 8) lid handle, 9) aluminum foil barrier, 10) 100 watt light bulb, 11) porcelain socket (sealed against box surface with silicone caulk, 12) outlet box, 13) cord and plug, 14) peat moss tray, 15) inspection window (bonded to lid with silicone caulk) over cutout, 16) lid brace, and 17) lid. The foil or flashing barrier (9) is made by affixing (with aerosol adhesive) a continuous aluminum foil strip (5-8 cm wide) near the inside-top of the box. Similarly, lower ventilation holes (2) require a foil barrier to prevent the escape of very small crickets. The box should be covered (inside and outside) with an oil-base paint in order to protect the wood from moisture.

High humidity appears to favor normal shedding of the exoskeleton by growing crickets. However, extremely high humidity promotes mold growth which is undesirable. To compensate for periods of low humidity, a clean tray of moist peat moss can be kept in the box.

To collect crickets, place a tall, wide-mouth, smooth-sided pitcher or similar vessel on the floor of the box. Lift the cardboard packing material (or metal cans) and knock the crickets into the pitcher.

Cost considerations. — The initial investment in materials (plywood, hardware, etc.) needed to construct and operate a three box colony is about $100.00. The crickets reared in this system will use from 120-150 kilograms of rabbit feed and 45 kilograms of whole potatoes each year. Thus, the estimated annual food cost is approximately $60.00. About one-fourth cubic meter of peat moss (at a cost of about $64.00/m^3) will be used annually in egg trays. Two starter orders of 1,000 adult crickets each (at approximately $15.00/thousand) will be required. Therefore, the investment and operating costs for the first year are around $200.00. The operating cost in subsequent years is about $100.00 per year. The boxes have a life expectancy of at least three to five years.

Servicing (cleaning, feeding, propagating, etc.) requires less than 15 minutes each day (one day can be skipped each week without significant harm). *Failure to maintain regular servicing of the boxes will result in greatly reduced cricket production.*

Assuming that the colony will produce about 2,000 crickets per week, more than 100,000 crickets will be realized annually. The equivalent number of crickets from a commercial supplier would cost approximately $1,500.00 annually. Moreover, commercial suppliers occasionally can not guarantee the safe arrival of orders shipped during periods of extremely hot or cold weather.

II. Tadpole rearing system

Rearing tanks. — Conventional aquaria make convenient containers in which to rear most anuran tadpoles. A tank (*e.g.*, 116 liter size) should be equipped with an aeration device (air stone), filter, gravel bed, and cover (canopy). Figure 3 illustrates the system of rearing tanks used in this laboratory.

Rearing procedure. — Fill the bottom of the tank to a depth of about eight to 10 centimeters with thoroughly washed (autoclaving is recommended) stream gravel or crushed limestone (about 1-1½ cm dia.). Next, fill the tank to within five to eight centimeters of the top with tap water. Add an aeration stone and air-driven filter (available from tropical fish stores, *etc.*). Use clear polyvinylchloride tubing for air hoses as the latex type soon rots. If a compressed air line is available, it can be used to supply the air stone and filter. Gang valves can be used to control the rate of air

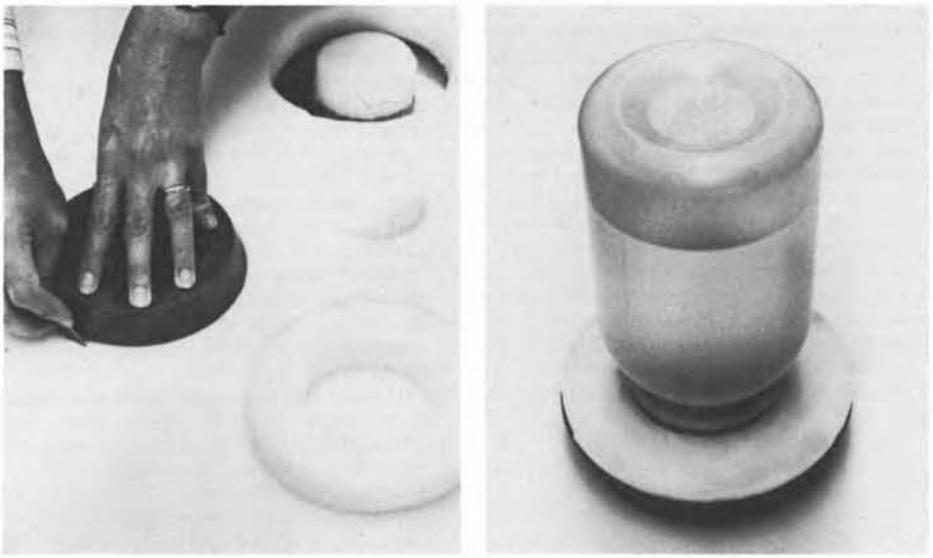

Figure 2. Preparation of the cricket waterer. Invert the waterer device on a piece of one inch thick polyurethane foam (available at fabric stores). Press down firmly and cut the foam by following the edge of the waterer with a sharp razor blade. Repeat this procedure in order to make the inside cutout, this time using the bottle cap as a template. Wash the foam ring insert thoroughly before use. Fill the bottle with tap water and prime the foam insert. Once in operation, rinse (do not use detergent) the foam insert every other day. The adult crickets will deposit eggs in the foam ring and these soon decay. Replace the insert about every two months (or as conditions dictate).

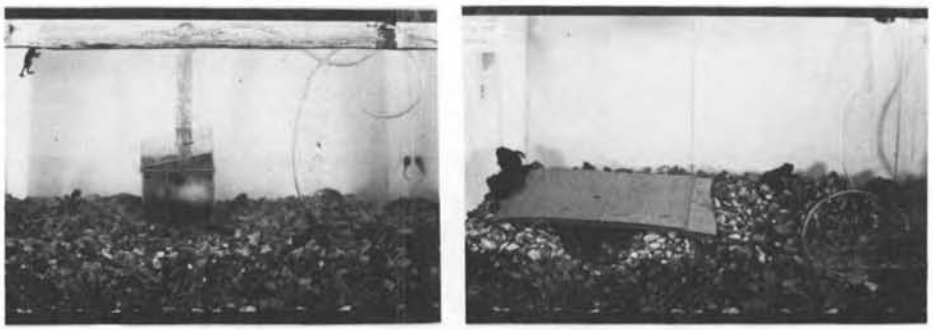

Figure 3. The tank systems used in rearing tadpoles (left) and transformed frogs (right). Pieces of gravel or crushed stone used in tanks containing transformed animals should be sufficiently large that they are not ingested by feeding frogs.

flow into the tank. A ballast jar containing water will trap oil contaminating the air supplied by some compressor systems. The miniature compressor units sold by tropical fish stores can also be used. Permit the tank to "season" with the air supply operating for two days, then *"seed" the tank with several cubic centimeters of bottom debris from a healthy pond.* Avoid the introduction of obvious predators to the tank. The addition of several snails at this time will contribute to a clean tank system as the snails will consume much of the food not used by the tadpoles. Permit the tank to stand for one week with aeration. Where necessary, several tanks can be supported on a framework of 2 X 4's against a wall. The room (or tank water temperature) should be about 20-23° C. A photoperiod of 12:12 was used for rearing both tadpoles and transformed frogs. If embryos or newly hatched tadpoles are to be added to the tank, reduce the air flow through the filter for the first two weeks of operation. This will prevent the small tadpoles from being drawn into the filter apparatus. Alternatively, glue a fine mesh plastic screen across the air filter intake to prevent entry of small tadpoles. Although a 116 liter tank will support several hundred very small tadpoles, after a few weeks, the number should be reduced to about 25-40 individuals. Crowding results in poor growth and development (Richards, 1962). It also contributes to disease problems. Add distilled or deionized water (in small increments) to the tank to compensate for evaporation and replace the polyester filtering material about once each month (or as conditions dictate).

Rabbit chow suspended in a mixture of agar and gelatin was used to feed the tadpoles. The formulation is as follows. Mix 750 cubic centimeters of rabbit chow in one liter of boiling water until the pellets disaggregate. To a second liter of boiling water, add 62 grams of agar while stirring and then add 41 grams of gelatin to the boiling agar-water. Finally, add the hot chow-water mixture to the agar-gelatin-water and stir thoroughly. Pour the mixture into a shallow tray (2-3 cm deep) and place in a refrigerator until it solidifies. Then, cut the material into blocks using the edge of a spatula. Place several blocks in plastic sandwich bags and freeze. Thaw each bag before use, break the individual blocks into portions, and drop into the tank. This formulation (adapted from one developed at the Amphibian Facility, University of Michigan) greatly reduces the chance that the tank water will be fouled by bacterial growth resulting from accidental overfeeding. It also provides the tadpole food in a form that is convenient. Feed the tadpoles every other day using large enough portions per tank so that a little remains about 24 hours after feeding. None should remain in 36 hours. Remove and discard any portion remaining in a tank for more than 48 hours. When waste material accumulates excessively in the crevices between pieces of stone, the tank should be drained (by siphoning) and cleaned (rinsed and refilled). This does not normally occur more often than about every two to four months.

Cost considerations. — The initial investment in tanks, filters and related paraphernalia is modest in comparison to the expense of buying commercially available setups designed for rearing tadpoles. Tanks of the 116 liter size range in price from about $30.00-$50.00 each. Glass top covers are about $12.00-$15.00 per tank. Filters and air stones add approximately $6.00-$8.00 per tank. Gravel (or crushed stone) costs are not significant. Thus, the investment per tank can be as little as $50.00-$70.00. The cost will be greater if it is necessary to purchase compressors and/or build a framework to support multiple tanks. The estimated cost of chow, agar, and gelatin needed to feed tadpoles from hatching through transformation (2½-4 months) is about $2.00 per 100 individuals. Replacement cost for spun polyester (for use in filters) and air stones is about $4.00 per tank per year of operation. Servicing operations (Feeding, filter replacement, tank cleaning, etc.) average about fifteen minutes per day (for 10 tanks).

III. Frog rearing system

Rearing tanks. — The tanks used to rear frogs from the time of metamorphosis through maturity are a modification of the tadpole tank system (refer to Figure 3). Prepare a tank with a gravel bed as described previously. (Pieces of gravel or crushed stone should be of sufficiently large size to prevent ingestion by feeding frogs). Add sufficient tadpole-tank water to bring the water level to within about two to four centimeters of the gravel surface. In one corner, place an air stone beneath the water level and cover with gravel. Most adult anurans (e.g., leopard frogs) require a moist environment; they do not need water in which to swim. Place one or two large rectangular pieces of cardboard, clay flower pot, or clay tile over a depression formed in the gravel so that the frogs will be able to crawl beneath them. Position the top cover on the tank (keep closed) and seal any large cracks with duct tape. This is not only a safeguard against escape by larger frogs; it is very important that the tank environment be kept reasonably

humid at all times for moist-skinned anurans.

Rearing procedure. — An aquarium, so arranged, will support as many as 20-25 frogs measuring four to six centimeters in snout-vent length. Many more smaller frogs can be kept successfully in tanks of this size. Very large frogs should be limited to about 10 or fewer per tank. Segregate frogs on the basis of size. Relatively large frogs are cannibalistic on their smaller tankmates. Replace the cardboard in the tanks when it begins to foul or decay. Add small increments of tap water periodically to compensate for evaporation. If the water level is too high or too low over an extended period, leopard frogs will die. Feed the frogs two or three times each week. Collect crickets suitable to the size of the frogs being fed. Feeding frogs with the largest crickets that they can ingest will maximize the mass productivity of the cricket colony. Newly transformed leopard frogs can handle two or three week old crickets easily.

To determine the number of crickets necessary for a feeding, simply add to each tank about five to eight crickets per frog. If some crickets remain after 24 hours, cut back feeding, and vice versa. Excessive numbers of large crickets in tanks of recently transformed frogs can be detrimental in that the crickets sometimes feed on the frogs. Tanks should be cleaned about every three to four months. Simply remove the frogs, rinse the tank thoroughly and reestablish the water level.

This method has been used to rear many leopard frogs through successive generations in this laboratory. No vitamin or mineral supplements of any sort were provided, however, they might be useful. Such adjuncts to normal feeding can be sprinkled onto a container of crickets before introduction to the frogs.

Do not handle frogs excessively. No evidence of disease was noted in any of the frogs reared (from eggs) using this method. However, some individual frogs that were handled frequently developed inflammations on the body surface and soon died. Other individuals in the same tanks were not affected. Do not introduce wild-caught specimens into tanks of laboratory-reared frogs unless the natural specimens have been quarantined for a month or more beforehand.

Cost considerations. — The expense for tanks and glass covers (see tadpole cost considerations) is the only major cost pertinent to rearing transformed frogs (cricket costs were considered earlier). A plastic, small animal cage, available from biological supply houses, costing about $10.00 per unit is an economical and useful substitute for conventional glass aquaria. Air stones, air tubing and gravel account for $2.00-$3.00 per tank annually. In this study, it was possible to rear the transformed tadpoles using only two tanks in addition to those containing tadpoles. Eighteen tanks were stocked with recently hatched tadpoles. The first of the tadpoles transformed in about 10 weeks. These were toe-clipped for identification and placed into two additional (frog rearing) tanks. As more tadpoles transformed, they too were placed in the nineteenth and twentieth tanks. Soon, several of the tadpole aquaria were empty (of tadpoles). These were drained and prepared for metamorphosing frogs. As transformed frogs were utilized for experiments, tanks were freed for starting more tadpoles. This procedure reduces costs considerably where it applies to a specific protocol.

REMARKS

In the course of establishing the frog rearing methodology described here, many varied approaches were tried. This design was judged the best because of simplicity, low cost, and the convenience of having the entire operation (cricket colony, tadpoles, and frogs) at one location. Commercially available frog rearing systems, although quite attractive, are generally both expensive and inflexible. Their design is often cumbersome for servicing operations and they require frequent cleaning and/or a continuous-flow water and drain system. Most such container designs are more appropriate for the short-term holding of anurans than for a rearing operation. Greenhouse frog rearing (see methods section of Frost and Bagnara, 1977) is: relatively expensive (initial investment); unsuitable in many geographic regions (high heating-cooling costs); and inconvenient (tadpoles and crickets generally must be kept elsewhere). Moreover, a greenhouse is difficult to subdivide in situations where there is a need for segregation of specimens. The system described in this report offers dependably high frog generation potential, relatively modest cost, and minimal servicing operations. Access to specimens is uncomplicated and segregation according to experimental design is easily achieved.

ACKNOWLEDGMENTS

The author wishes to thank C. M. Richards and G. W. Nace for sharing valuable techniques developed at the Amphibian Facility, The University of Michigan, Ann Arbor. George M. Malacinski (and the Axolotl Colony, Indiana University) provided some of the equipment and facilities used in the study. Portions of this project were undertaken while the author was affiliated with the University of Arizona, Tucson, and subsequently with Indiana University, Bloomington. The author would like to acknowledge the support provided by the Center for Biomedical Research — The University of Kansas. This work was incidental to studies for which support was provided by grants (DEB-7620340, DEB-7911561 and DEB-8108266) from the National Science Foundation.

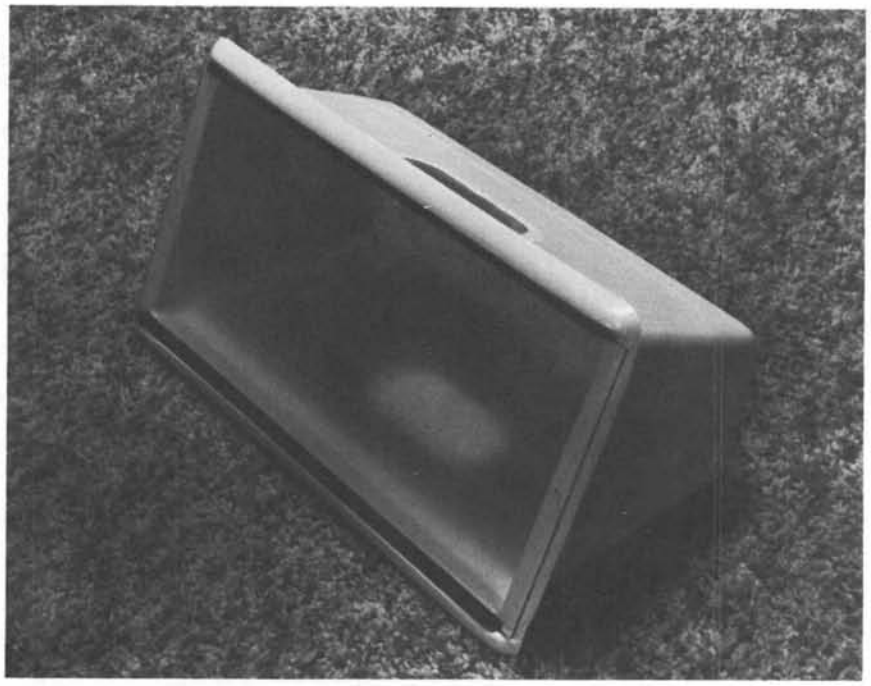
A REVIEW OF THE DISEASES AND TREATMENTS OF CAPTIVE TURTLES

by

James B. Murphy and Joseph T. Collins



This book is a review of the vast literature on diseases and treatments of captive turtles, with direct reference to approximately 600 citations in the text plus a supplemental bibliography of over 300 titles. Chapters consist of: ***Environmental Factors Affecting Captive Turtles; Bacterial, Viral, Mycotic and Algal Infections of Captive Turtles; Protozoan Infections of Captive Turtles; Helminth Infections and Arthropod Infestations of Captive Turtles; Dietary Deficiencies of Captive Turtles; Non-Infectious Diseases and Injuries of Captive Turtles; Surgical Procedures for Turtles; and Necropsy Techniques and Specimen Collection for Turtles.*** An index to scientific names used in the text is included.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

NEWSNOTES

AMPHIBIANS AND REPTILES IN PENNSYLVANIA

Amphibians and Reptiles in Pennsylvania, by C. J. McCoy. 1982. $4.00/copy plus $1.00 postage and handling (PA residents add .24 tax). Order from Publications Secretary, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, PA 15213. Carnegie Museum of Natural History Special Publication No. 6.

This 91 page book presents a concise and interesting account of the Pennsylvania herpetofauna. Written by Carnegie Museum's Curator of Herpetology, the book contains a checklist of species, species accounts, a complete bibliography and a distribution atlas. This last is especially handy as it shows points of record within counties, rather than just a single, central dot within a county of record. This type of map is very tedious work to prepare, but the information content greatly enhances its utility for users. It will be of interest to teachers, herpetologists and anyone interested in the wildlife of the northeastern states. ●

REPTILES AND AMPHIBIANS OF SOUTHEASTERN NATIONAL FORESTS

Published April 19, 1982, this is a U.S. Forest Service In-Service Publication prepared by Monte E. Seehorn (Regional Fisheries Biologist, Southern Regional Office U.S.F.S., 1720 Peachtree Rd., N.W., Atlanta, GA 30367). The inventory was compiled from both literature search and fieldwork, and is available *gratis* from the Regional Office. An extensive bibliography is provided, as is a tabular reference to species of the region listed by national forest. Species recognized as endangered, threatened, *etc.* are so marked. ●

ABSTRACTS OF PAPERS OF RALEIGH MEETINGS AVAILABLE

Abstracts of the papers presented at the 25th Anniversary meeting of the Society for the Study of Amphibians and Reptiles and the 30th Annual meeting of the Herpetologists' League are available at cost. This was the largest Herpetological meeting in the world in 1982, consisting of 178 contributed papers.

Order from: *Publications Secretary*

Price: Within continental U.S.A. - $6.00
Overseas - $6.50

Book Rate Postage *Included.* ●

1983 ANNUAL MEETING

Dates for the 1983 SSAR Annual Meeting at The University of Utah (jointly with HL) are 7-12 August. Rooms will be available beginning 6 August. Details will be announced later. ●

THE SMITHSONIAN FOREIGN CURRENCY PROGRAM

This national research grants program, offers opportunities for support of research in Burma, Guinea, India, and Pakistan in the following disciplines:

Anthropology, Archeology and related disciplines,
Systematic and Environmental Biology,
Astrophysics and Earth Sciences, and
Museum Programs.

Grants in the local currencies of the above listed countries are awarded to American institutions for the research of senior scientists. Collaborative programs involving host country institutions are welcome. Awards are determined on the basis of competitive scholarly review. The deadline for submission is November 1 annually. For further information write the Foreign Currency Program, Office of Fellowships and Grants, Smithsonian Institution, Washington, D.C. 20560, or call (202) 287-3321. ●

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

CAUDATA

NECTURUS MACULOSUS (Mudpuppy). USA: WISCONSIN: Dunn Co: Red Cedar River, directly beneath Interstate Highway 94 bridge (T-28N, R-13W, Sec. 13). 17 May 1980. University of Wisconsin-Madison, Zoological Museum (UWZH 22503). Caught at 18:00 on hook and line in 12 feet of water over rocky substrate by Walter Koenst, with James Stewart. A nightcrawler was used as bait. This is the first published record for Dunn County (Vogt, R. C. 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, 205 pp.).

Submitted by **PHILIP A. COCHRAN,** Laboratory of Limnology, University of Wisconsin, Madison, Wisconsin 53706. ●

SALIENTIA

HYPEROLIUS LATERALIS. KENYA: Rift Valley Province: Nandi Hills District: 8 km SW of Nandi Hills Town, 2100 m. 14 September 1980. Steve Reilly. Verified by R. C. Drewes, California Academy of Sciences (CAS 152769-70). First known record for the province. Extends the known range 46 km to the east and just into the Kenya highlands, and is a new altitude record. These two specimens represent the easternmost limit for this species.

Submitted by **STEVE M. REILLY,** Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901. ●

RANA CATESBEIANA (Bullfrog). USA: WISCONSIN: Sawyer Co: shallow, weed-choked bay off Hayward Lake, an impoundment of the Namekagon River (T41N,R9W, Sec. 27). 28 May 1982. Philip A. Cochran. University of Wisconsin-Madison, Zoological Museum (UWZH 22504). Female. Several adults and many tadpoles were observed. This is the first published record for Sawyer County (Vogt, R. C. 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, 205 pp.).

SCAPHIOPUS BOMBIFRONS (Plains Spadefoot). USA: ARKANSAS: Pope Co: Holla Bend National Wildlife Refuge, ca 6.4 km SE Dardanelle, T6N, R20W, S24. 7 and 9 June 1978. L. Shott and Arkansas Tech Univ. herpetology class. Identified by M. V. Plummer. Verified by D. C. Forester. Collection of Glyn Turnipseed (GDT 193, 194). First record for the state. Nearest locality is near Muskogee, Oklahoma, ca 240 km W (AMNH #59708-710; J. H. Black, pers. comm.) Although primarily limited to the Great Plains, the range of *S. bombifrons* extends substantially to the east on the floodplain of the Missouri River (Johnson, 1977. The Amphibians of Missouri, Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. No. 6). Holla Bend is located within the Arkansas River floodplain. These specimens could be flood-borne waifs brought down the nearby Arkansas River. However, the adult specimen (SVL = 42 mm) and the 2 juveniles (SVL's 17 and 19 mm) suggest a local breeding population. GDT 193 was previously reported as *S. holbrooki* (Turnipseed, 1980. Geographic distribution: *Scaphiopus holbrooki hurteri,* Herp. Rev. 11:1).

Submitted by **MICHAEL V. PLUMMER** and **GLYN TURNIPSEED,** Department of Biology, Harding University, Searcy, Arkansas 72143 and Department of Biology, Arkansas Tech University, Russellville, Arkansas 72801. ●

SCAPHIOPUS COUCHI (Couch's Spadefoot). USA: TEXAS: Archer Co: 3.5 km W of junction of FM 2650 on FM 1954. 21 May 1982. Rocky Ward. Verified by E. G. Zimmerman. North Texas State University Herpetological Collection (NTSUHC A-55). This is the first record for the county which is at the northern part of a hiatus in north central Texas (Raun and Gehlbach, 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by **ROCKY WARD,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

TESTUDINES

CHRYSEMYS CONCINNA (River Cooter). USA: TEXAS: Rains Co: 8.7 km W of Emory on Texas Rt. 35. 18 June 1982. C. T. McAllister. Verified by R. Ward and E. G. Zimmerman. North Texas State University Herpetological Collection (NTSUHC R-683). This specimen (a female with eggs) found DOR is a new county record and appears to be another *C. c. hieroglyphica* x *texana* intergrade (see Myers, S. 1982. Geographic distribution: *Chrysemys concinna.* SSAR Herp. Review 13 (1):24). Intensive collecting in the North Sabine River drainage and the zone presently separating the ranges of these subspecies may reveal populations for the adjacent counties and east Texas distributional hiatus (Raun and Gehlbach, 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2; Conant, R. 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston).

Submitted by **CHRIS T. MCALLISTER,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

GRAPTEMYS GEOGRAPHICA (Map Turtle). USA: ARKANSAS: Pike Co: Caddo River at U.S. Hwy. 70. 4 October 1969; 10 June 1970; 24 July 1973. R. McKown and J. Needham. West Texas State University Museum of Natural History (WTSU 449, 1069, 1079, 1080, 1081, 1651, 1652, 1664, 1696). ARKANSAS: Marion Co: Buffalo River near Rush. 2 August 1974; 15 September 1974. M. Geishler. (WTSU 7026, 7027). Verified by F. C. Killebrew. New county records. Caddo River specimens extend range 110 km W and 110 km N of nearest localities in Saline and Lafayette Counties. (Dellinger and Black, 1938, Occas. Papers Univ. Ark. Mus. 1, 47p; H. H. Schwardt, 1938, Ark. Exper. Station Bulletin No. 357, 47p.). Buffalo River specimens extend range 90 km W of nearest locality in Fulton County. (H. G. Gowling, 1957, Occas. Papers Univ. Ark. Mus. 3, 51p.).

Submitted by **F. C. KILLEBREW,** Department of Biology, West Texas State University, Canyon, Texas 79016. ●

TRIONYX SPINIFERUS (Spiny Softshell Turtle). USA: WISCONSIN: Sawyer Co: Hayward Lake, an impoundment of the Namekagon River (T41N, R9W, Sec. 27). 25 May 1982. Philip A. Cochran and Frank Pratt (Wisconsin Department of Natural Resources). University of Wisconsin-Madison, Zoological Museum (UWZH 22505). One of two females collected in an unbaited fyke net, along with several *Chelydra serpentina* and many *Chrysemys picta.* This is the first published record for Sawyer County (Vogt, R. C. 1981. Natural history of amphibians and reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, 205 pp.). The specimen was collected at a locality farther north than any Wisconsin specimens examined by Vogt (1981), although he considered as valid records from two localities in Douglas County farther north. A series of artificial impoundments of the Namekagon River may have facilitated a northward range extension or increased population levels of *T. spiniferus* during historical times through the creation of a variety of large riverine habitats, although direct movements may be impeded.

Submitted by **PHILIP A. COCHRAN,** Laboratory of Limnology, University of Wisconsin, Madison, Wisconsin 53706. ●

SAURIA

ANOLIS SAGREI (Brown Anole). USA: VIRGINIA: James City Co: 6 km NW Williamsburg at Lightfoot. 14 December 1978. W. R. Hoilman and L. H. Westermann. Verified by J. C. Mitchell. National Museum of Natural History (USNM 225102). Found on a potted *Schefflera* plant in the greenhouse of the Williamsburg Pottery Shop. This specimen (male, 40mm SVL) rafted northward on potted plants believed to have originated on Estero, Lee County, Florida. This is probably an isolated occurrence and establishment of a breeding disjunct population in this area is unlikely.

This record confirms that *A. sagrei* can disperse long distances by rafting aboard ornamental plants (Godley, et al., 1981. Herp. Rev. 12(3):84-86) and suggests that dispersal may be more widespread than previously recognized. Are there disjunct populations outside peninsula Florida?

SERPENTES

BOA CONSTRICTOR IMPERATOR (Boa Constrictor). MEXICO: SONORA: Near Tetuchie (sometimes spelled Tetuachi), 16 km south of Arispe (sometimes spelled Arizpe). Elev. approximately 750 m. 30° 15' N, 110° 15' W. 7 June 1979. William H. Baltosser. Photo verification (Univ. Kansas Museum of Natural History Color Slide #s 7094-7095), photos verified by Joseph T. Collins. Dead in sandy wash surrounded by non-native tree tobacco *(Nicotiana glauca);* presumably killed by something other than human, no footprints in area surrounding snake, only small unidentifiable depressions in sand. Apparent predation on neck, approximately 30 cm of flesh stripped from area just behind head, head and rest of snake basically intact. Remains measuring approximately 110 cm not collected, several photographs obtained (Figures 1 and 2).

Figure 1. Closeup of head and neck region showing apparent signs of predation.

Figure 2. Overall view of snake showing severed head-neck region along with the rest of the body.

To my knowledge, this represents the northernmost locality of occurrence for this species which ranges from Tamaulipas and Sonora southward along both coasts, including Yucatan, to South America (Smith and Taylor, 1966. Herpetology of Mexico: Annotated checklists and keys to amphibians and reptiles. Reprint, Eric Lundberg, Ashton, Maryland. pp. 24-25). Formerly, the northernmost record for this species in Sonora was reported to be 78 km north of Hermosillo (Zweifel and Norris, 1955. American Midl. Nat. 54:230-249). Pope (Pope, 1973. The Giant Snakes: The natural history of the boa constrictor, the anaconda, and the largest pythons. Alfred A. Knopf, New York, New York. pp. 25-27) stated that the northernmost place where this species has been found in Sonora was within 240 km of the Arizona border. According to Bogert and Oliver (Bogert and Oliver, 1945. Bull. American Mus. Nat. Hist. 83:297-426), from time to time there have been unverified reports of this snake in southern Arizona, but since none were found far from human habitations, it was not certain whether these were native, or accidental importations. The Tetuchie record reported here places the species within 120 km of the Arizona border and approximately 95 km northeast of the previous northern record.

LEPTOTYPHLOPS DULCIS (Texas Blind Snake). USA: COLORADO: Baca Co: 36 km S, 19 km W Pritchett, Furnish Canyon, T34S R50W SE¼ Sec. 32, 1433 m. 31 May 1982. B. Lapin and G. Hammerson. Identified by G. Hammerson, verified by H. M. Smith. Univ. Colorado Mus., Boulder, UCM 54216 (complete shed skin). First documented record for the state. Freshly shed skin found under rock on SW-facing slope. Locality is 10 km N, 8 km W of Oklahoma Panhandle record (Webb, 1970, Reptiles of Oklahoma, Univ. of Oklahoma Press, Norman).

Submitted by **BETH P. LAPIN,** Colorado Natural Heritage Inventory, 1550 Lincoln #110, Denver, Colorado 80203, and **GEOFFREY A. HAMMERSON,** Department of Environmental, Population, and Organismic Biology, University of Colorado, Boulder, Colorado 80309. ●

LEPTOTYPHLOPS DULCIS DISSECTUS (New Mexico Blind Snake). USA: KANSAS: Sumner Co: collected *ca.* 2 km SW Caldwell, Sec. 15-16, R3W, T35S on 15 May 1982 by K. J. Irwin. Verified by J. T. Collins. University of Kansas Museum of Natural History (KU 192197). First record for Sumner County, extends the known range *ca.* 70 km E of nearest Kansas record (Collins, 1982, Amphibians and reptiles in Kansas), and *ca.* 105 km N of northeasternmost Oklahoma record (Webb, 1970, Reptiles of Oklahoma). The specimen is the most northeastern record for the species. Taken under sandstone rock on west-facing slope of hillside. Associated species of amphibians and reptiles: *Gastrophryne olivacea, Terrapene ornata, Cnemidophorus sexlineatus, Holbrookia maculata, Diadophis punctatus, Lampropeltis getulus, Sonora semiannulata,* and *Tantilla nigriceps.*

TRIMORPHODON UPSILON (Broad-banded Lyre Snake) MEXICO: SONORA: 32 km (by Mex. Hwy. 2) E Caborca (DOR). 15 April 1961. J. W. Heinrichs. Identified by J. R. Ottley. Brigham Young University (BYU 21178). Extends the range approximately 470 km northward from the Alamos-Guirocoba area of southern Sonora. The specimen, an adult female (571 mm total length), has 22 dorsal blotches which, though lower than the minimum given by Smith (1941, Proc. U. S. Natl. Mus. 91:149-168), are within the range Zweifel and Norris (1955, Amer. Midland Nat. 54: 230-249) reported for specimens from Guirocoba. Prior to this discovery this species had only been taken in subtropical habitats, several specimens (BYU 36807-36808, 41160) having been found in the desert scrub/thorn forest transition between Navojoa and Alamos. In addition to the specimen of *T. upsilon* reported here, the tree frog *Hyla wrightorum,* which is generally associated with mountain valleys, has been taken near Caborca at Trincheras (AMNH 53033). The discovery of these species in the same region of the Sonoran Desert suggests that these specimens may represent relictual populations, isolated during expansion of the desert during the retreat of Pleistocene glaciers. The stomach of BYU 21178 contains a partially digested sand lizard *(Callisaurus draconoides).*

SECOND FIND OF *PSEUDEMYS RUBRIVENTRIS* AT IPSWICH, MASSACHUSETTS, AND REFUTATION OF THE NAUSHON ISLAND RECORD

Waters (1962) described the find of *Pseudemys rubriventris* skeletal remains in an Indian shell heap at Ipswich, Essex County, Massachusetts originally reported by Bullen (1949). Waters proposed that this, and other evidence, supported his suggestion that this species was at one time continuously distributed along the coastal plain upon the formerly emergent continental shelf. He went on to speculate that Essex County populations may have been extirpated by former human inhabitants of area. In fact, Bullen (1949) did indicate the red-belly shell fragments (identified by Dr. Loveridge at the MCZ) were Indian food remains. Waters (1962) also stated that a dead specimen of *P. rubriventris* was found on Naushon Island, Dukes County, Massachusetts in 1944 (MCZ 46965).

On 23 July 1981 George Gavutis and Mike Bauer found the shell of an unfamiliar turtle near shore in Stage Island Pool at the southern end of Plum Island, Ipswich, Essex County, Massachusetts on the Parker River National Wildlife Refuge. Both Gavutis and Bauer work at the Refuge and had never seen anything like this specimen before. I subsequently identified it as *Pseudemys rubriventris* and deposited it in the Museum of Comparative Zoology (MCZ 162300). Their find was within 2 km of the Clark Pond site at Great Neck (Bullen, 1949). Later, I examined the Clark Pond specimen at the Peabody Foundation Museum at Phillips Andover Academy and asked Dr. Walter Auffenberg to look at it as well. He and I concluded that this material does include *P. rubriventris* (a subadult) and *Terrapene* peripheral bones.

The exciting possibility exists that a colony of *P. rubriventris* has survived undetected in Ipswich since at least 1500 Y.B.P. (the probable age of the Clark Pond artifacts according to Dr. R. S. MacNeish of the Peabody Foundation). Previous rumors of large basking turtles near the Ipswich River Audubon Sanctuary, Topsfield, Massachusetts (Dr. J. D. Lazell, *personal communication*) suggests the possible occurrence of these animals at least 15 km upriver from Plum Island Sound. Shell dimensions of MCZ 162300 are: carapace length = 284.5 mm, plastron length = 264 mm, and shell height = 124 mm. This specimen, an adult female, has a nuchal underlap ratio comparable to those of a set of 37 Plymouth red-bellies I recently examined. Some of its carapacial scutes are intact and the second costals bear the moderately forked distinct light transverse bar which is typical of Plymouth County *rubriventris.* The shell is not scarred, nor does it show evidence of irregular growth which might otherwise indicate captive rearing. It appears the specimen was

a wild endemic that died during the winter of 1981.

After examining the Naushon specimen (MCZ 46965) I became suspicious of its identification; its proportions and markings were not at all like those of nearly 200 Massachusetts red-bellies I have handled in the last three years. Dr. Walter Auffenberg examined this specimen at my request and he agrees with me completely that it is not *Pseudemys rubriventris*. He stated that its markings, streamlining, low profile, bone thickness, and carapacial flaring are more similar to *P. concinna* or *P. floridana*. He was not sure exactly which of these it is, but he said it is definitely not a Florida turtle. It is probable that this individual was introduced to Naushon Island after initial tenure as someone's pet. Two of my assistants and I have unsuccessfully scoped and trapped the waters of Naushon during the past three summers; we also talked with Naushon residents. No one interviewed had ever seen a red-bellied turtle on the Island, and at least two of the people we met were good naturalists quite familiar with the Island's turtle fauna. Lacking hard evidence to the contrary, I must conclude that *P. rubriventris* does not presently inhabit Naushon; and it quite possibly never did.

ACKNOWLEDGMENTS

I commend Mssrs. Gavutis and Bauer for having the presence of mind to retrieve the shell, and I thank Roger Hogan, OES specialist for the U.S. Fish and Wildlife Service, for calling their discovery to my attention. Dr. Auffenberg's generous and prompt accommodation of my urgent requests for assistance is deeply appreciated. José Rosado of the MCZ and Dr. R. S. MacNeish of the Peabody Foundation for Archaeology obligingly afforded me access to the aforementioned material in their collections.

COMMENTS ON THE DISTRIBUTION OF *AMBYSTOMA TALPOIDEUM* (HOLBROOK) IN TENNESSEE

Published range maps (Shoup 1964, Conant 1975) typically depict *Ambystoma talpoideum* as an animal of the Coastal Plain Physiographic Province in the southeastern United States, with several populations known from Appalachian provinces in Alabama, Georgia, North Carolina, and Tennessee. Shoup (1964) speculated that most of the non-Coastal Plain populations are continuous with west Tennessee Coastal Plain populations by way of the Cumberland and Tennessee River drainages. Although shown as continuous on his range map, populations in western North Carolina and eastern Tennessee were considered by Shoup to be disjunct. In contrast, Conant (1975) considered most non-Coastal Plain populations disjunct from the continuous Coastal Plain range of the species. Shoup (1964) stated that the distribution of *A. talpoideum* is in need of study, and his range map shows central Tennessee as an area requiring further study.

Since Shoup (1964) and Conant (1975), additional data on Tennessee populations have been acquired. The objectives of this paper are to update and describe further (1) distribution of *A. talpoideum* in Tennessee, (2) habitats being utilized, and (3) areas in need of further study.

Eighty-four specimens from 26 collecting sites were examined from Austin Peay State University (APSU), Carnegie Museum of Natural History (CMNH), Field Museum of Natural History (FMNH), Louisiana State University Museum of Zoology (LSUMZ), Memphis State University Museum of Zoology (MSUMZ), Tennessee Technological University (TTU), U.S. National Museum (USNM), University of Tennessee Vertebrate Zoology Collection, Knoxville (UTKVZC), and The University of Tennessee, Martin (UTM).

The distribution of *A. talpoideum* in Tennessee, as determined in this study, is shown in Fig. 1. Populations are known from the Coastal Plain, northern portions of Western Highland Rim, eastern edge of Eastern Highland Rim, Cumberland Plateau west of the Sequatchie Valley, and the extreme southern end of the Unaka Mountains (Fig. 1). In agreement with Shoup (1964) and Conant (1975) we believe Tennessee populations in the Unaka Mountains to be disjunct and possibly continuous with the western North Carolina populations reported by Braswell and Murdock (1979). Shoup (1964) considered all middle Tennessee populations to be continuous with those in west Tennessee. In contrast, Conant (1975) illustrated the range of *A. talpoideum* in eastern middle Tennessee as two disjunct entities. Based on locality data gathered for this study, Cumberland Plateau and Eastern Highland Rim populations in middle Tennessee are considered to form a single, continuous geographic unit which is thought to be disjunct. However, these populations are possibly continuous with the population reported by Mount (1975) from Jackson County, Alabama. In concurrence with Shoup (1964) and Conant (1975), we believe populations in the northern portion of the Western Highland Rim to be continuous with those in the west Tennessee Coastal Plain. Further fieldwork is needed to determine the extent of distribution in the Eastern Highland Rim and the possibility of the species occurring continuously across north central Tennessee.

Previous descriptions of suitable habitat for *A. talpoideum* in Tennessee have been

(305) 724-9542

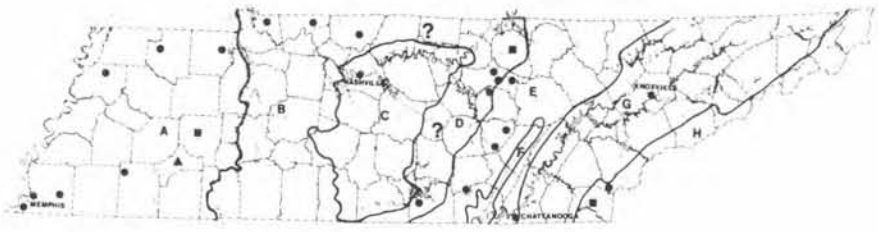

Fig. 1. Distribution of *A. talpoideum* and outline of physiographic features of Tennessee as modified from Miller (1974). Solid circles: localities from which specimens were examined and may denote more than one collecting site. Solid triangle: literature record believed valid. Solid squares: county literature records — locality data lacking. Question marks: areas in need of further investigation. Area A denotes the Coastal Plain, B -Western Highland Rim, C - Central Basin, D -Eastern Highland Rim, E - Cumberland Plateau, F - Sequatchie Valley, G - Valley and Ridge, and H - Unaka Mountains.

extremely brief: Endsley (1954) took one specimen "in the river bottom near Henderson"; Gentry (1955) found individuals in "small ponds" in Henry and Overton Counties; Brigham et al. (1967) collected *A. talpoideum* "from a road adjacent to Booger Swamp, a flooded woodland" in Putnam County; and Scott and Snyder (1968) "observed the species breeding in a woodland pond" in Montgomery County. Clearly, more information is needed for adequate portrayal of the conditions under which the species exists near the northern limits of its distribution. Based on recent field studies by the authors, A. C. Echternacht, and students at The University of Tennessee, the following habitat data are presented. All wetland types mentioned are those proposed and described by Carter and Burbank (1978). On the Western Highland Rim, the species has been found mainly in forested swamps and on one occasion (David H. Snyder pers. comm.) in a lower bottom-land hardwood forest surrounding an abandoned river channel. On the Eastern Highland Rim and Cumberland Plateau, forested swamps, shrub swamps, and dead woody swamps were found to be frequent environs of the species. In Van Buren County, individuals were taken near strip mine ponds.

Specimens Examined

DYER CO.: Maxey, (2 specimens) - USNM 28391-28392. FRANKLIN CO.: Mingo Swamp, 2.3 km (airline) south of Broadview, 15 July 1978, (2) - UTKVZC 04136, 04603. A CHECKLIST OF THE HERPETOFAUNA OF BUTTE COUNTY, THE BUTTE SINK AND SUTTER BUTTES, CALIFORNIA

This checklist summarizes some 3,000 reptile and amphibian records from various museums and contributors, in addition to over 2,000 personal observations made over five years (1973-1978). A detailed publication on the herpetofauna of this region is in preparation, but this checklist may be useful to workers and agencies until that manuscript is published (Hayes, MS in prep.).

Each species listed is vouchered by at least one museum specimen or recognizable photograph. Photographs are color slides deposited both at California State University, Chico and in the senior author's personal collection. The area covered includes all of Butte County and portions of Glenn, Colusa and Sutter Counties in the Butte Sink, bordered by the Sacramento River and Sutter Buttes.

Although this summary outlines the actual herpetofauna existing within this region, it does not pretend to be complete, but provides baseline data for future work. The region presents numerous herpetological problems, since much of it has been poorly explored. Among species unrepresented is the plethodontid salamander *Hydromantes*, whose occurrence is suggested in foothill limestone outcrops in the Lime Saddle region of Butte County. Recent discoveries of coastal plant disjuncts, such as Licorice Fern *(Polypodium glycyrrhiza)*, suggest that disjunct populations of amphibians such as *Dicamptodon ensatus, Ascaphus truei* and *Aneides flavipunctatus* may be discovered. Further, the Sutter Buttes pose interesting distributional problems, such as the presence of *Cnemidophorus tigris* and the absence of *Masticophis lateralis*, two species closely associated with chaparral vegetation in northern California. Many such problems may be solved by additional field work. It is hoped that future workers will append existing distributional data, since a thorough understanding of an organism's distribution is of essential value in augmenting the knowledge of its biogeography, ecology and evolution.

Major classification categories are those of Goin and Goin (1971) for amphibians and Romer (1956, 1966) for reptiles. Brame (1967) was followed for subordinal groupings of salamanders, and Dowling (1975) was followed for snake classification to the subfamilial level. Tribal classification of colubrids was omitted because these categories have not been well defined and are largely in a state of flux at this time (A. Savitsky, pers. comm.). Common and scientific names follow "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" by Collins *et al.* (1978). Brief comments on distribution are restricted to the checklist area cited.

Class AMPHIBIA - Amphibians
Superorder LEPOSPONDYLI
Order CAUDATA (URODELA) - Salamanders
Suborder AMBYSTOMATOIDEA
Family AMBYSTOMATIDAE - Mole Salamanders

1) *Ambystoma californiense* - California Tiger Salamander
Recorded at a single location in a somewhat alkaline vernal pool at Grey Lodge wildlife refuge in southwestern Butte County.

2) *Ambystoma macrodactylum sigillatum* - Southern Long-toed Salamander
Recorded from lakes, ponds and meadows in the higher reaches of the drainages of Butte Creek and the Little West Branch of the Feather River in northwestern Butte County. All localities are above 1300 m (4330 ft).

Family PLETHODONTIDAE - Lungless Salamanders

3) *Ensatina eschscholtzi platensis* - Sierra Nevada Ensatina
Recorded from most of Butte County over 600 m (2000 ft), but occuring in shaded canyons down to 400 m (1330 ft). The lower limit of its distribution approximates the lower limit of the distribution of Ponderosa Pine *(Pinus ponderosa)*.

4) *Batrachoseps attenuatus* - California Slender Salamander
Found largely in foothill woodland and chaparral areas below 600 m (2000 ft). Its distribution corresponds closely with that of the Interior Live Oak *(Quercus wislizenii)*. It is unrecorded north of Rock Creek in Butte County and has not yet been found in adjacent Tehama County. This species occasionally extends onto the valley floor via well-developed fingers of riparian woodland. It is recorded in the Sutter Buttes. Only rarely sympatric with *Ensatina*, it can be found coexisting with *Ensatina* at the lower fringe of yellow pine forest.

Suborder SALAMANDROIDEA
Family SALAMANDRIDAE - Newts

5) *Taricha granulosa granulosa* - Northern Roughskin Newt
Recorded in the drainage of the Little West Branch of the Feather River and all drainages northward above 500 m (1670 ft).

6) *Taricha torosa sierrae* - Sierra Newt
Found in virtually all drainages below 800 m (2660 ft), but is largely absent where drainages span the valley floor. This species exists in sympatry with *T. granulosa* in the drainages of Butte Creek and the Little West Branch of the Feather River between 500 m (1670 ft) and 800 m (2660 ft). It is not recorded in the Sutter Buttes.

Superorder SALIENTIA
Order ANURA - Frogs and Toads
Suborder ANOMOCOELA
Family PELOBATIDAE - Spadefoot Toads

7) *Scaphiopus hammondi* - Western Spadefoot
Known from higher terrace-type vernal pools and ephemeral drainages on the valley floor between the Pentz area and Honcut in Butte County. All localities are between 30 m (100 ft) and 100 m (330 ft).

Suborder PROCOELA
Family BUFONIDAE - Toads

8) *Bufo boreas halophilus* - California Toad
Bufo boreas halophilus X *boreas* (intergrade)
Virtually ubiquitous throughout the checklist area at all elevations. Intergrades *(B. b. halophilus* X *boreas)* are found in the region of Chico and northward. It is absent above 1800 m (6000 ft) because of lack of breeding habitat.

Family HYLIDAE - Treefrogs

9) *Hyla regilla deserticola* - Pacific Treefrog
Virtually ubiquitous throughout the checklist area at all elevations. This species is also absent above 1800 m (6000 ft) because of lack of breeding habitat.

Suborder DIPLASIOCOELA
Family RANIDAE - True Frogs

10) *Rana aurora draytoni* - California Red-legged Frog
Known only from 2 locations, 2 deep-water springs in the vicinity of Bidwell Bar at approximately 300 m (1000 ft) of elevation.

11) *Rana boylei* - Foothill Yellow-legged Frog
Found in most drainages from the valley edge at 90 m (300 ft) to slightly over 1500 m (5000 ft). It is absent from the valley floor, but occurs in the Sutter Buttes.

12) *Rana cascadae* - Cascades Frog
Found in the higher reaches of the Little West Branch of the Feather River and similar drainages to the north over 1300 m (4330 ft). A single anomalous location on the Anderson Fork places this species at 230 m (770 ft) in a stream through a chaparral location. The locality of this specimen is suspect as no further individuals have been found.

13) *Rana catesbeiana* - Bullfrog
The only established introduced species in the area covered by the checklist. It is ubiquitous at virtually all permanent water locations in the valley and the lowest foothill reaches of streams. This species is also found at isolated outposts at higher elevations (i.e. Kunkle Reservoir, Concow Lake).

14) *Rana muscosa* - Mountain Yellow-legged Frog
Found in the higher reaches of Butte County drainages over 1300 m (4330 ft). It is sympatric with *R. cascadae* at virtually all known locations. Sympatry with both *R. boylei* and *R. cascadae* is recorded at a single location on the Little West Branch of the Feather River.

Class REPTILIA - Reptiles
Subclass ANAPSIDA
Order CHELONIA (TESTUDINES, TESTUDINATA) - Turtles
Suborder CRYPTODIRA
Superfamily TESTUDINOIDEA
Family TESTUDINIDAE
Subfamily EMYDINAE - Pond Turtles

15) *Clemmys marmorata marmorata* - Northwestern Pond Turtle
Occurs in most ponds, reservoirs and low gradient drainages below 1000 m (3330 ft).

Subclass LEPIDOSAURIA
Order SQUAMATA - Lizards and Snakes
Suborder LACERTILIA (SAURIA) - Lizards
Infraorder IGUANIA
Family IGUANIDAE - Iguanid Lizards

16) *Sceloporus occidentalis occidentalis* - Northwestern Fence Lizard
Ubiquitous throughout the checklist area below 1900 m (6330 ft). Its distribution becomes increasingly spotty with increased elevation.

17) *Sceloporus graciosus graciosus* - Northern Sagebrush Lizard
Found from the highest point in Butte County at Humboldt Peak, 2127 m (7082 ft), down to 170 m (570 ft). The distribution of this species becomes extremely spotty below 300 m (1000 ft). This species is frequently sympatric with *S. occidentalis*. It occurs in the Sutter Buttes above 150 m (500 ft).

18) *Phrynosoma coronatum frontale* - California Horned Lizard
Occurs at a few isolated outposts in low grassland and open woodland sites in the vicinity of Oroville and below Paradise. These localities range from 120 m (400 ft) to 450 m (1500 ft).

Infraorder ANGUINOMORPHA
Superfamily ANGUOIDEA
Family ANGUIDAE
Subfamily GERRHONOTINAE - Alligator Lizards

19) *Gerrhonotus multicarinatus multicarinatus* - California Alligator Lizard
Found virtually throughout the checklist area below 1000 m (3330 ft).

20) *Gerrhonotus coeruleus palmeri* - Sierra Alligator Lizard
Gerrhonotus coeruleus palmeri X *shastensis* (intergrade)
Recorded virtually throughout the checklist area above 900 m (3000 ft). It is absent in regions of dense Red Fir *(Abies magnifica)* forest. Sympatry with *G. multicarinatus* is recorded only in Butte Creek canyon. The northeastern portion of the county is an area of intergradation between *G. c. shastensis* and *G. c. palmeri*. Individuals referable to the *palmeri* subspecies are found from the Middle Fork of the Feather River and southward.

Infraorder SCINCOMORPHA
Family SCINCIDAE - Skinks

21) *Eumeces skiltonianus skiltonianus* - Western Skink
Found in scattered sites throughout the checklist area below 1500 m (5000 ft). On the valley floor it is often restricted to the riparian woodland belts.

Family TEIIDAE - Whiptails

22) *Cnemidophorus tigris mundus* - California Whiptail
Scattered isolates are found in regions of chaparral and mixed chaparral-foothill woodland associations between 200 m (670 ft) and 650 m (2160 ft) in Butte County. This species also occurs in the Sutter Buttes between 140 m (470 ft) and 550 m (1830 ft) in isolated pockets.

Suborder SERPENTES (OPHIDIA) - Snakes
Infraorder ALETHINOPHIDIA
Superfamily BOOIDEA
Family BOIDAE - Boas and Pythons
Subfamily ERYCINAE

23) *Charina bottae bottae* - Pacific Rubber Boa
At scattered locations in open coniferous forest above 600 m (2000 ft). It occurs also in shaded canyons down to 400 m (1330 ft).

Superfamily CAENOPHIDIA (COLUBROIDEA)
Family COLUBRIDAE - Colubrid Snakes
Subfamily COLUBRINAE - Colubrine Colubrids

24) *Coluber constrictor mormon* - Western Yellowbelly Racer
Found throughout the checklist area, absent only from heavily shaded coniferous forest. This species becomes very infrequent above 1800 m (6000 ft).

25) *Lampropeltis getulus californiae* - California Kingsnake
Recorded from the valley floor up to 700 m (2330 ft) within the checklist area. Infrequent above 600 m (2000 ft), its distribution corresponds closely with the proximity of available free water.

26) *Lampropeltis zonata multicincta* - Sierra Mountain Kingsnake
Found primarily between 400 m (1330 ft) and 1300 m (4330 ft), infrequently up to 1500 m (5000 ft). In protected canyons, this species is found as low as 350 m (1170 ft). Although it has been recorded in close proximity with *L. getulus* (ca. 1 kilometer (.6 mile)), true sympatry is unrecorded for the checklist area. This species is also unrecorded from the drainages north of Butte Creek and is absent from the Sutter Buttes.

27) *Masticophis flagellum ruddocki* - San Joaquin Coachwhip
Recorded only from the Sutter Buttes between 30 m (100 ft) and 150 m (500 ft).

28) *Masticophis lateralis lateralis* - California Striped Racer
Closely associated with chaparral and brushy vegetation between 100 m (330 ft) and 650 m (2160 ft). It is unrecorded from the Sutter Buttes.

29) *Pituophis melanoleucus catenifer* - Pacific Gopher Snake
Found at all elevations below 1800 m (6000 ft). This species is absent from heavily shaded coniferous forest and becomes infrequent above 1700 m (5660 ft).

30) *Rhinocheilus lecontei lecontei* - Western Longnose Snake
Recorded only from the Sutter Buttes between 30 m (100 ft) and 150 m (500 ft). The existing records are from localities with loose sandy-loam substrates.

Subfamily NATRICINAE - Natricine Colubrids

31) *Thamnophis sirtalis fitchii* - Valley Garter Snake
Found at all elevations below 1800 m (6000 ft). This species would probably extend its range to the highest point in the county at 2127 m (7082 ft), but requisite habitat is absent above 1800 m. Its distribution closely corresponds to lentic sites with emergent vegetation providing cover.

32) *Thamnophis couchi couchi* - Sierra Garter Snake
Found at elevations from 100 m (330 ft) to near 1700 m (5660 ft) within the checklist area. This species, like *T. sirtalis*, would probably extend its range higher in elevation if requisite habitat existed. Closely associated with rocky stream courses, this subspecies of *T. couchi* is absent from the valley floor portion of the checklist area. It is unrecorded from the Sutter Buttes.

Thamnophis couchi gigas - Giant Garter Snake
Restricted to the valley floor freshwater marsh habitats, primarily below 40 m (130 ft). The interface region between the *gigas* and *couchi* subspecies lies at the valley-foothill edge between 40 m and 100 m (330 ft). The degree to which these two subspecies intergrade is incompletely known.

33) *Thamnophis elegans elegans* - Mountain Garter Snake
Found from the lowest foothill slope at 60 m (200 ft) to the highest elevations within the checklist area (Humboldt Peak at 2127 m (7082 ft)). Infrequent above 2000 m (6660 ft), it is absent from the valley floor and unrecorded in the Sutter Buttes.

Subfamily XENODONTINAE - Xenodontine Colubrids

34) *Contia tenuis* - Sharp-tailed Snake
Found from the low foothill slope at 60 m (200 ft) to 700 m (2300 ft). This species is very infrequent above 700 m. Its distribution is spotty and local, corresponding well with the availability of loose surface cover. It is also unrecorded from the Sutter Buttes.

35) *Diadophis punctatus pulchellus* - Coralbelly Ringneck Snake
Found on the foothill slope from 60 m (200 ft) up to possibly 1000 m (3330 ft). The upper limit of distribution is poorly known. It is found much less frequently above 700 m (2300 ft). Its distribution corresponds well with the distribution of Big Leaf Maple *(Acer macrophyllum)* and California Bay *(Umbellularia californica)* within the elevation range cited. Recorded from the Sutter Buttes, it is generally absent from the valley floor. A single record exists for Grey Lodge, but this is undocumented by further collections. Notably, true sympatry with *Contia tenuis* has not been recorded for the checklist area.

36) *Hypsiglena torquata nuchalata* - California Night Snake
Found on the lower foothill slope between 60 m (200 ft) and 300 m (1000 ft). Distribution of this species correlates well with the presence of Blue Oak *(Quercus douglasii)* on an at least partially rocky substrate. It is unrecorded from the Sutter Buttes.

Family Viperidae - Vipers and Pit Vipers
Subfamily Crotalinae - Pit Vipers

37) *Crotalus viridis oreganus* - Northern Pacific Rattlesnake
Found throughout the checklist area up to 1800 m (6000 ft) and infrequently recorded above 1500 m (5000 ft). It is generally absent from *open* grassland on the valley floor.

ACKNOWLEDGMENTS

Numerous individuals have contributed information to help make these data more complete. We wish to express our warmest thanks to all these contributors even though we cannot acknowledge all individually. Thanks are due to the following individuals who contributed specimens and/or data from their respective institutions: John Brode, John Cowan and George Hanson (Cal Fish & Game); John Simmons, Robert Drewes and Alan Leviton (CAS); David Wake, Gloria Wurst and Kristine Tollestrup (MVZ); Robert Bezy and John Wright (LACM); Doug Ruth and Jim Berrian (SDMNH), and Robert Livezey (CSUS). Special thanks are due Thomas Rodgers for constant encouragement and the use of critical field notes, Robert Schlising and Craig Guyer for critical review of the manuscript and Joan Warner for her typing.

HERPETOLOGICAL MONOGRAPH No. 1

Published by The Herpetologists' League

Race With Extinction

Herpetological Field Notes of J. R. Slevin's Journey to the Galapagos 1905–1906

A CLASSIC, PERSONAL ACCOUNT OF THE HISTORIC CALIFORNIA ACADEMY OF SCIENCES EXPEDITION TO THE GALAPAGOS ARCHIPELAGO. THIS VOLUME BELONGS ON YOUR SHELF IF---

- YOU ARE A GALAPAGOPHILE OR VISITOR TO THE ISLANDS. The volume is illustrated richly with previously unpublished photos from the Expedition. It documents the condition of the islands in 1905, and includes a map of the course of the Expedition along with appendices detailing the ship's itinerary geographically and chronologically.
- YOU HAVE EXPERIENCED THE FRUSTRATIONS OF LONG-TERM FIELD WORK. Slevin's notes are an amusing and informative chronicle of the triumphs, mishaps, and relationships of the personnel of the Schooner "Academy."
- YOU ARE INTERESTED IN THE GALAPAGOS TORTOISES. Page after page of ecological data and measurements are published here for the first time.

---------- ORDER FORM ----------

Available to Herp. League members for $8.75

Available to nonmembers, after 6 Aug. 1982, for $12.00

(For shipment other than by surface mail--book rate, include an additional $1)

Please send me ____ copies of Herpetological Monograph No. 1, *Race With Extinction*.

I enclose a check in U.S. Currency or equivalent in the amount of $____.____, payable to THE HERPETOLOGISTS' LEAGUE.

Societas Europaea Herpetologica

Amphibia-Reptilia

The SEH was founded in 1979 by herpetologists from 8 European countries to encourage closer collaboration between European and Non-European scientists. Its publication AMPHIBIA — REPTILIA is a multidisciplinary journal devoted to all aspects of herpetology, to further the interchange of knowledge and ideas between specialists on different subjects, ranging from the use of biochemical technics in herpetological research to electron microscopy, from amphibian and reptilian genetics to the fossil history of the modern amphibians and reptiles, including systematics and taxonomy as well as behaviour, physiology and ecology.
AMPHIBIA — REPTILIA publishes high-quality original papers, short articles on new methods and ideas in progress, book reviews and news of the SEH.

"With current exchange rates for the West German Mark, membership in SEH costs approximately $31."

BOOK REVIEW

Identification Guide to Pennsylvania Snakes by C. J. McCoy, Jr.; Illustrated by Michael Antonoplos. Price $1.50 + 25¢ postage (PA residents add 9¢ sales tax). Available from Benedum Resource Project, Section of Education, Carnegie Museum, Pittsburgh, PA 15213.

This booklet, similar in format to guides covering Kansas and Florida herps, provides novices with quick, accurate identification of Pennsylvania snakes. More limited in scope than the Kansas or Florida guides, the book is well laid out and introduced to the user. The drawings of species are adequate for most final identifications (PA is blessed with a snake fauna consisting of relatively few and fairly distinct species) and the addition of range maps is an asset. While a couple of the introductory statements could incorrectly be taken as applying to snakes in general, rather than to Pennsylvania species, I found nothing to fault the publication and recommend it highly to Pennsylvanians and residents of adjacent states.

GEORGE R. PISANI
University of Kansas

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

REPRODUCTION IN CAPTIVE ARUBA ISLAND RATTLESNAKES, *Crotalus unicolor*

The Aruba Island rattlesnake *Crotalus unicolor*, is probably derived from a generalized *Crotalus durissus* stock and is found only on Aruba Island off the coast of Venezuela. The species is considered rare by the International Union for Conservation of Nature and Natural Resources (IUCN). Kauffeld and Gloyd (1939) reported some data on a captive-born litter from a wildbred female. Klauber (1972) reported some data on *C. unicolor* born at San Diego Zoo. From 1973 through 1980 nine live litters and one stillborn litter were born at the Houston Zoological Gardens.

A pair of *C. unicolor* (Male A, Female A) collected on Aruba Island were received on 27 May 1969 from a dealer. Male C was received from a dealer on 21 June 1976 and Female B was obtained from the Gladys Porter Zoo sometime previous to 4 May 1976. Collection data are not available for these last two specimens. Subsequent births at the Houston Zoological Gardens produced Male B and Female D on 2 June 1975, Male D on 6 June 1973 and Female C on 6 September 1973.

Some specimens were exhibited in a glass-fronted enclosure (80 X 90 X 140 cm) with a gravel substrate. Large rocks and plastic plants provided cover. Light was from four 20 W Vita-lites (Duro-test Corp.). Temperature averaged 28° C and the relative humidity was *ca.* 85 percent. Specimens off exhibit were kept in various size aquaria with paper substrate and hide boxes. Vita-lites were not used for these specimens. Temperature averaged 28° C with a relative humidity of *ca.* 75 percent.

All specimens were maintained under a 14L:10D photoperiod throughout the year. Water was available *ad libitum* and adult specimens were fed mice every 14-21 days. The specimens were occasionally separated and reintroduced and periodically misted with water in attempts to induce reproduction.

Specimens were weighed on a triple-beam balance and lengths were obtained using the squeeze box technique (Quinn and Jones, 1974).

Copulation was observed on only two occasions, 16 October 1978 (Male C, Female D) and 17 Septmeber 1980, (Male B, female unknown); however, courtship behavior has been variously recorded from 26 July to 21 October. The duration of copulation for the 17 September observation was between 7.5 to 10.0 hrs. The 16 October occurrence was not timed. Klauber (1972) reported copulation occuring on 14 and 21 September in captive *C. unicolor* at the San Diego Zoo. No year was given.

Dates of birth, number of young and their measurements are given in Table 1. Birth dates varied from 27 April to 6 September with births occuring most often in May and June (seven of nine cases). Klauber (1972) reported 5 April, 13 May, 5 and 27 June as

TABLE 1. Data for newborn *Crotalus unicolor*.

Parents		Date	# of young	Total length(mm) $\bar{x}$(range)	Tail length(mm) $\bar{x}$(range)	Weight(g) $\bar{x}$(range)
Female A	Male A	9/6/73	5	—	—	—
A	A	6/9/74	4	—	—	—
A	A	6/2/75	5	—	—	—
A	?	5/23/77	4	283[1]	21[1]	—
A	D	5/13/78	3	276(269-290)	19(17-22)	13.6(12.5-15.0)
Female B	Male A	5/4/76	3	—	—	—
Female C	Male D	4/27/78	4	271(260-282)	21(19-26)	13.6(13.0-14.0)

D	B	5/16/80	2	235(231-239)	20(19-20)	11.9(11.6-12.1)

[1]Only one young measured

dates of birth for *C. unicolor* at the San Diego Zoo. It was not stated if all births were the result of captive copulation.

At the Houston Zoo, the number of live young in nine litters was 2-5 ($\bar{x}$=3.6). If the number of stillborn are included to compute potential litter size the number is 3-5 ($\bar{x}$=4.3), and if the number of infertile eggs expelled is then added the number is 3-8 ($\bar{x}$=4.6). The above data include the 2 May 1979 birth of five stillborn and three infertile eggs to Female A. Kauffeld and Gloyd (1939) reported a wild-bred female that gave birth to five young that were stillborn or died shortly after birth. The female died after parturition and contained seven more dead young for a total of 12, which is seven more than the maximum number of live and stillborn for a single birth in this study. Klauber (1972) reported litters of six, seven, nine and 15 young, which is from one to ten more than the maximum number of live and stillborn young reported for a single birth in this study. Based on our data from Female A, age did not appear to be a factor in litter size. In fact, she had progressively fewer young in 1977 and 1978, and on 13 May 1979 she gave birth to five stillborn. She also expelled single infertile eggs in 1974, 1977 and 1978 and three in 1979 along with the five stillborn. This seems to indicate a reduction in reproductive potential with increasing age. Female A was apparently mature (based on size) when received in 1969 and must have been at least 11 years old in 1979. Size of the female can not be shown to be a factor in litter size since Female D was 746 mm in total length when she produced two live young and one stillborn, while the specimen of Kauffeld and Gloyd (1939) was 758 mm, only 12 mm longer. Klauber (1972) gave no length for a mature female. Measurements are not available for any other females at the Houston Zoo at the time of parturition.

The total length of all new-born that were measured during this study was 231-290 mm ($\bar{x}$=269; N=12) while the total length of all stillborn young measured was 211-295 mm ($\bar{x}$=243; N=10). The two smallest newborn were 231 and 239 mm total length and may have been premature since they both died of yolk impaction and unabsorbed yolk sac 3-4 wks after birth. The measurements reported by Kauffeld and Gloyd (1939) of three newborn (187-205 mm; $\bar{x}$-198 mm) apparently indicate a premature birth, since the measured specimens and all others born at the same time or recovered from the dead mother were dead, or died, shortly after birth. Klauber (1972) reported two lengths for newborn *C. unicolor*. The smallest specimen measured 230 mm, the average of an unspecified number of young was 235 mm. Assumedly, these measurements represent *C. unicolor* born at the San Diego Zoo. The tail lengths of all measured live-born young at the Houston Zoo was 17.0-25.5 mm ($\bar{x}$=20.0; N=10) and the weight was 9.2-15.1 g ($\bar{x}$=13.0; N=12). Kauffeld and Gloyd (1939) and Klauber (1972) did not report specimen weights.

The coloration and pattern of newborn and juveniles was as reported by Kauffeld and Gloyd (1939) and Klauber (1972).

ACKNOWLEDGMENTS

We are indebted to the staff of the Department of Herpetology, Houston Zoological Gardens for assistance during this study.

PREDATORY BEHAVIOR OF "NERVOUS" RATTLESNAKES, *Crotalus durissus terrificus*

It has previously been reported that striking prey induces high rates of tongue flicking in rattlesnakes (Chiszar, Radcliffe, and Scudder, 1977; Chiszar, Radcliffe, and Smith, 1978) and cantils (Chiszar, Simonsen, Radcliffe, and Smith, 1979). Further, it has been argued that strike-induced tongue flicking (also called chemosensory searching) is a modal action pattern which normally brings the snake into the vicinity of its now dead prey so that swallowing behavior can be released by cues arising from the carcass (see Burghardt, 1970, for a review of the literature on chemical cue utilization by reptiles). Accordingly, when a predatory strike occurs, chemosensory searching should be released and the rest of the predatory chain should unfold. Often a rattlesnake which has consistently refused food can be instigated to eat if it can be made to exhibit chemosensory searching consequent to striking a prey object even for defensive reasons. This strengthens our belief that strike-induced chemosensory searching is a modal action pattern and that the predatory sequence is a response chain in which execution of each element predisposes the snake to engage in the next element. Although strong sequential dependencies exist between some components of the response chain (Dullemeijer, 1961; Duvall et al., 1978), variations in the usual temporal ordering of components are known to occur and even to be characteristic of individual snakes. For example, some specimens will exhibit chemosensory searching and ingestion without first striking prey (Klauber, 1956; Patten and Banta, 1980). Accordingly, it seems most appropriate to regard rattlesnake predatory behavior as an open reaction chain as opposed to a closed or fixed program (Mayr, 1974).

Some rattlesnakes are especially defensive and exhibit ritualized threatening behaviors because of very slight movements of keepers or their equipment. Even if striking prey acts to induce chemosensory searching in such a snake, the animal's attentional priorities may override this effect. Defensive behaviors rather than chemosensory searching may occur, or, a mixture of both behaviors may emerge. The present experiment was designed to evaluate this possibility.

METHOD AND MATERIAL

Subjects were six specimens of *Crotalus durissus terrificus*. The animals were approximately three yr. old and had been in captivity for 2½ yrs. Three of these snakes were extremely defensive, exhibiting coiling, rattling, and head hiding upon being approached by experimenters. The other three animals showed such responses only upon strong provocation and usually exhibited investigatory behavior (Chiszar et al., 1976) when experimenters approached the cages (see also Armstrong and Murphy, 1979).

Each snake was observed in two conditions. In Condition A a mouse was suspended into the snake's cage for three s and held just out of striking range. Condition B was exactly like Condition A except the snake was allowed to strike the mouse at the end of three s. In both cases the mouse was removed at once, and immediately a perforated plastic box containing a different, envenomated, dead mouse was placed into the cage approximately 20 cm from the snake. This procedure has two advantages as compared to testing

snakes with the mouse used in the initial presentation: (1) Since in Condition A the snakes did not have an opportunity to strike, any envenomated mouse used in the subsequent test of chemosensory searching must be struck by a different snake. By using mice envenomated by different (but conspecific) snakes in all tests (including Condition B), we hold this factor constant, otherwise source of envenomation would be confounded with our two experimental conditions; (2) By having an envenomated mouse ready prior to all tests we are able to begin the chemosensory searching observations immediately after the three s mouse presentations. This eliminates any confounding delays that would be occasioned by waiting for mice to die in Condition B.

All tongue flicks emitted by the snakes were recorded for five min following introduction of the dead mouse. The two conditions were administered on successive days and snakes had been fasted for two mo prior to these tests.

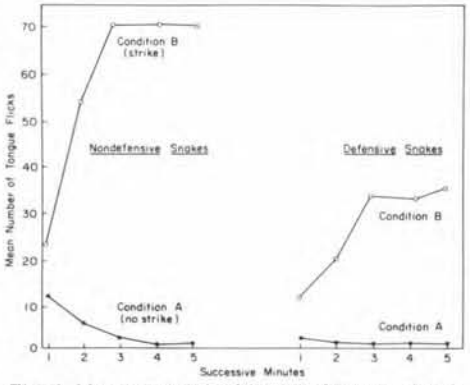
RESULTS

Figure 1 presents mean number of tongue flicks emitted by the defensive and nondefensive snakes in each of the test conditions. It is obvious that striking induced chemosensory searching in both groups ($F = 38.21$, $df = 1/4$, $P < .01$).

The defensive snakes showed a much smaller chemosensory searching effect after striking than the nondefensive snakes; in fact, the linear and quadratic components of the strike and no-strike functions were significantly smaller in the former than in the latter animals ($F = 3.90$, $df = 2/16$, $P < .05$).

DISCUSSION

That striking induced chemosensory searching even in the defensive snakes is evidence of the reliability of this phenomenon. However, the reduced magnitude of the effect of striking in the defensive snakes required



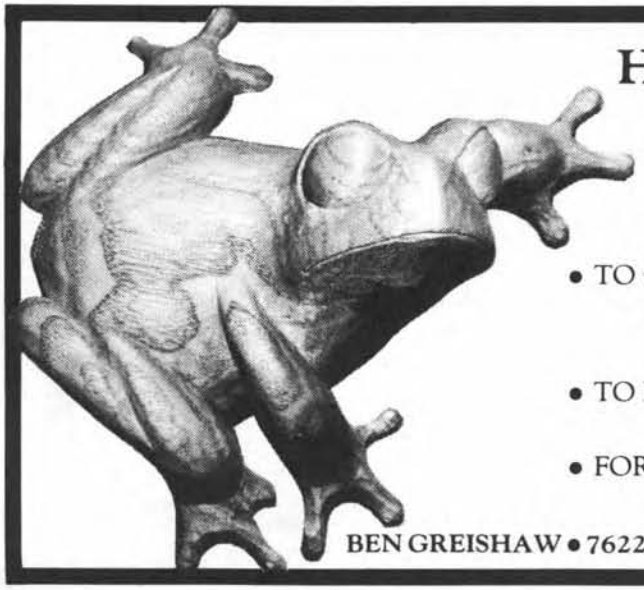


Fig. 1. Mean number of tongue flicks emitted by three nondefensive and three defensive specimens of *C. d. terrificus* during five successive minutes after seeing a mouse (Condition A) and after seeing and striking a mouse (Condition B).

explanation, assuming that the present finding based on small samples can be regarded as a characteristic difference between defensive and nondefensive rattlesnakes. Our view is that defensive snakes have lower thresholds for activation of ritualized threat responses and that the occurrence of these responses interferes with the simultaneous occurrence of predatory behavior, including the emission of high rates of tongue flicking. In support of this idea it should be said that after the tests described in this paper, all snakes were offered the mouse they had struck at the start of Condition B. The three nondefensive snakes accepted their prey immediately and all had finished swallowing within 10 min. The defensive snakes began to eat only after the experimenters left the room, and they finished swallowing after 40 min. Probably the latter snakes would not eat as long as a person was in the laboratory, indicating that (1) these snakes responded defensively to stimuli that were ignored by the nondefensive snakes, and (2) striking prey did not produce a complete shift in attention from threat-eliciting to feeding-related cues. The last point is especially interesting for three reasons. First, we had previously believed that striking prey was an unconditional releaser of chemosensory searching; this view must now be modified. Second, in our experience some defensive rattlesnakes have been switched completely into chemosensory searching by striking; these snakes would then swallow a dead mouse immediately upon encountering it, even if human observers remained nearby. Accordingly, it may be theoretically important to learn what distinguishes those defensive snakes that are induced to feed by striking a mouse from those that are not. Third, we believe it operationally useful to assume that when a rattlesnake strikes a mouse a search image (Croze, 1971; Dawkins, 1971, Tinbergen, 1960) is formed in the snake's central nervous system. The search image is conceptualized as a neural representation of an envenomated dead mouse, and its function is to provide the basis for the snake's ability to trail and locate the rodent carcass (Chiszar et al., in press). In essence, asserting the existence of a search image is tantamount to saying that the snake "knows what it is looking for." The search image is akin to a memory trace, and, as such, it is subject to decay over time. Our results indicate that the search image remains available for at least 30 min in most rattlesnakes, and considerably longer in some individuals (Scudder, in prep; Radcliffe and Chiszar, in prep). If we assume that allowing a snake to strike a mouse results in defensive reactions (because of the keeper's presence) and the activation of a predatory search image, we can hypothesize that the duration of defensive behavior will be a critical parameter. If the defensive reactions, which preclude most aspects of feeding behavior, outlast the search image, the snake may cause itself to lose the representation of its now dead prey. Since this representation appears to be a necessary condition for trailing and swallowing (Chiszar et al., 1977; Duvall et al., 1978), its loss may preclude ingestion. This may explain why some particularly defensive snakes never or rarely eat in captivity, even when they can be induced to strike a prey item.

PORTABLE – RECHARGABLE EMERGENCY LIGHT FOR VENOMOUS REPTILE AREAS

NEW! Available now from FurMont Reptile Equipment

The Streamlight SL-40 LITEBOX is an absolutely essential piece of professional high intensity emergency lighting equipment for anyone who keeps or handles venomous reptile species at night or in an enclosed area where daylight might not be available should the power fail and the lights go out.

SHOULD A POWER FAILURE OCCUR WHILE YOU HAVE A CAGE OPEN OR ARE HANDLING A SPECIMEN, THE LITEBOX WILL TURN ON IMMEDIATELY, FLOODING THE AREA WITH LIGHT SO THAT YOU MAY SAFELY PUT THE SPECIMEN AWAY AND LOCK THE CAGE.

The Litebox is also a completely portable quartz-halogen lantern that can be quickly removed from its rack to provide high intensity light wherever you need it for up to 8 hours on a single recharge. Since it is completely AC or DC rechargeable it may also be taken on extended or night trips to the field where it may be recharged through the cigarette lighter of a car.

The Litebox is used by a number of major zoos both in their reptile and other animal handling areas and it has proven invaluable in this service.

The Litebox is easy and fast to install (less than 5 minutes), requires no electrician to install it, will run 8 hours with its 8 watt flood** or 8 watt spot** (25,000 candlepower) lamp, 4 and 2/3 hours with the 12 watt flood** lamp or 2 and 3/4 hours with the 20 watt flood** lamp.

The price for the Litebox (with either beige or orange case of high impact ABS plastic—specify) complete with power failure sensing rack, AC charger, DC charger and your choice of lamp**(see above—specify) is $139.95 complete plus $4.00 shipping(surface) or $8.50(air) per unit. Other options available are Locking Racks (Add $5.00), Swivel Heads (Add $5.00) and Carrying Strap (Add 4.00).

Each Litebox has an unconditional 30 day money back guarantee so please feel free to order one for a personal evaluation.

If you would like to receive a data sheet for the Litebox, an applications booklet for the Litebox, or information on any of our other ultra-high intensity rechargeable handlights please phone or write:

STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES (Second Edition)

By Joseph T. Collins, Roger Conant, James E. Huheey, James L. Knight, Eric M. Rundquist and Hobart M. Smith

Available in summer 1982. The first edition of this reference, issued in 1978 as SSAR **Herpetological Circular** No. 7, quickly became a standard reference for herpetologists, biologists, zoos, museums, conservation organizations, wildlife societies, book publishers, and Federal and state wildlife agencies. This second, revised edition is an up-date listing over 1300 common and scientific names for species and subspecies of North American (north of Mexico) salamanders, frogs and toads, crocodilians, turtles, lizards, and snakes. New features in this edition (not in the 1978 version) are an appendix of Hawaiian amphibians and reptiles, the inclusion of the names of describers for all genera, species and subspecies, and the addition of a table comparing the number of currently recognized subspecies with those listed in earlier publications. The SSAR Committee on Common and Scientific Names (shown above) considered over 50 proposed changes for this edition, the majority of which were adopted.

TO ORDER SSAR HERPETOLOGICAL CIRCULAR NO. 12* . . . . $3.00 Payment in U.S. funds only

SEND ORDERS TO:
DR. DOUGLAS H. TAYLOR, DEPARTMENT OF ZOOLOGY, MIAMI UNIVERSITY, OXFORD, OHIO 45056 USA. Make checks payable to "SSAR;" receipt on request. A pricelist of other Society publications can be obtained on request from Dr. Taylor, including the **Journal of Herpetology, Herpetological Review, Contributions to Herpetology,** other **Herpetological Circulars, Catalogue of American Amphibians and Reptiles,** and the **Facsimile Reprints in Herpetology** series.

***Herpetological Circulars are no longer distributed free to SSAR members; individuals desiring copies of this and future numbers should place their orders as per the above instructions.**

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1978. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

AMPHIBIA/REPTILIA. HEMOPARASITES.

During the MPM Kuehn-Amazon Expedition (Oct.-Dec. 1974) 102 amphibians and reptiles were surveyed for hemoparasites. Samples were obtained at four different locations in Amazonian Peru; near Centro Union (CU), Iquitos (I), Mishana (M) and Yanamono (Y) (see Dixon and Soini. 1975. Milwaukee Pub. Mus. Contrib. Biol. Geol. No. 4:1-58.) Because customs policies were in a political flux we were unable to utilize scientific materials shipped into Peru. The study was completed with whatever materials obtainable and the quality of the slides permitted a reliable decision only on positive blood smears.

Blood was obtained by heart puncture or a caudal or limb stab with a disposable scalpel. Blood smears were air-dried, fixed in methanol and stored for later examination. Because, there is so little information concerning the distribution of many amphibian and reptile parasites (Ayala. 1978. J. Protozool. 25(1):87-100.), especially from Amazonia (Guerrero and Ayala. 1977. Rev. Inst. Med. Trop. São Paulo 19(5):283-288.) we present the results of the survey (Table I).

Funding for the MPM-Kuehn Amazon Expedition was provided primarily by the James H. Kuehn Research Fund, with supplemental funding via Friends of the Museum and Max Allen's Zoological Gardens. Dr. James R. Dixon, Sherman and Marge Ketcham, Robert Henderson, Janice Mahlberg and Pekka Soini assisted in various ways. Dr. William Duellman identified the hylid frogs.

GYMNOPHIONA

TYPHLONECTES COMPRESSICAUDUS (Aquatic Caecilian). **REPRODUCTION.** *Typhlonectes* is known to be viviparous, but little published information on captive reproduction is available. Breeding habits of *T. compressicaudus* have been described in detail (Murphy *et al.*, 1977, Copeia: 66-69), and a single young was produced at Cincinnati Zoo in 1970 (D. Jardine, pers. comm.) and died after approximately six weeks.

On 22 March 1981, the Oklahoma City Zoo obtained a female *T. compressicaudus*, which was housed in an aquarium with a male already in the collection. On 24 April 1981, the male died. No mating was observed during the brief interim they were together, and it is conceivable that the female arrived at the zoo in gravid condition. In late September, a few small protuberances were noticed along the flanks of the female, and during the evening of 2-3 October she gave birth to four young. These measured approximately 11, 12, 12, and 14 cm total length. The smallest retained the oviductal gill sac until midday, 4 October; the others shed this member shortly after parturition, prior to being discovered. All neonates were slate-black in colour, slightly lighter along the lateral grooves, and resembled thinner versions of the adult.

The young were transferred to an aquarium provided with undergravel filtration, several large, smooth rocks, and a layer of fine, coarse gravel. Water temperature ranged from 21.5-22° C. The first feeding of chopped earthworms was readily accepted; subsequently, they have taken whole young earthworms and tubifex worms. Each caecilian shed the entire skin six days after birth, and a second shedding followed by the 16th day.

The smallest specimen died in March 1982, and the other young were placed on public exhibit. They have since accepted young crickets, small snails and finely chopped horsemeat.

Prior to parturition, the female showed no unusual behavior and fed regularly on earthworms, snails and horsemeat. She escaped the week after giving birth and has since been assumed dead. While it is possible mating occurred at the zoo, it was not observed. Had the female arrived gravid, gestation of the young would have been at least six months.

CROCODILIA

ALLIGATOR SINENSIS (Chinese alligator). **REPRODUCTION/AGING.** A female *A. sinensis* was received 28 September 1937 by the National Zoological Park from the National Geographic-Smithsonian Institution Expedition to the East Indies. On 22 March 1976, she was sent to the Rockefeller Wildlife Refuge, Grand Chenier, Louisiana, for inclusion in a New York Zoological Park breeding program (Behler, J. 1977. Herp. Rev. 8(4):124-125). In August 1980, this female laid 21 eggs from which eight hatchlings were produced. This is the oldest, known-age crocodilian to successfully reproduce. The female is still alive in a breeding situation.

Submitted by **MICHAEL L. DAVENPORT,** Department of Herpetology, National Zoological Park, Washington, D.C. 20008 ●

CROCODYLUS CATAPHRACTUS (Slender-snouted crocodile). **REPRODUCTION/AGEING.** A "young adult" female *C. cataphractus* was received 7 August 1940 by the National Zoological Park from the Smithsonian-Firestone Expedition to Liberia. On 23 July 1980, she laid 18 eggs while on breeding loan to Metrozoo, Miami, Florida. Thirteen eggs were fertile; one egg hatched but the hatchling died within several days. The female is still alive in a breeding situation.

Though the literature is contradictory (Neil, W. T. 1971. The Last of the Ruling Reptiles.... pp. 1-486; Yadav, R. N. 1979. Int. Zoo. Yearb. 19:66-68; Yangprapakorn, U. *et al.* 1971. IUCN Publ. n.s. suppl. 32:98-101), the majority of authors and this note indicate that old crocodilians are capable of successful reproduction and should not be discounted from captive breeding programs.

This has been written through the cooperation of John Behler and Peter Brazaitis of the New York Zoological Park, Ted Joanen and Larry McNease of the Rockefeller Wildlife Refuge, and William Zeigler of Metrozoo.

SAURIA

HOLBROOKIA MACULATA (Lesser Earless Lizard). **COLORATION.** A small sample of *Holbrookia maculata* was collected from slopes of the east shore of Parker Canyon Lake, Huachuca Mountains, Cochise County, Arizona on 6-8 June, 1972. The habitat is at an elevation of about 1560 m. The sample consists of two males and four females, one of the latter being essentially patternless (Figure 1). The dorsal color of this specimen (UCM 54206) is a uniform grayish-brown. There is a diffuse longitudinal stripe on each side, gray in color, which replaces the faint lateroventral bars exhibited by the other females. The specimen differs in color from representatives of *H. m. ruthveni,* the Bleached Earless Lizard, in retention of the usual intensity of pattern background pigmentation. The ventral color of all specimens is white.

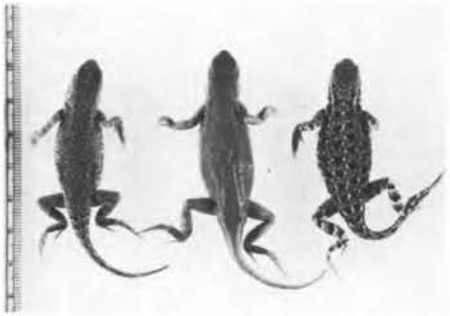

Fig. 1. Three female specimens of *Holbrookia maculata* from the vicinity of Parker Canyon Lake, Huachuca Mountains, Cochise County, Arizona illustrating representative color patterns present in the population (left, UCM 54210; center, UCM 54206; right, UCM 54207).

The correct subspecific identity is in doubt, although a short-tailed form is indicated. The tail/total length ratios for individuals with intact tails = males: 45 and 49%; females: 44, 45, and 48%. Smith's (1946, Handbook of lizards. Comstock., p. 115) key provides an identity of *H. m. approximans,* but the specimens lack the small, light dorsal spots that appear to characterize individuals of this subspecies. In addition, the specimens have supraocular-frontal scale contact, a character used by Smith and Taylor (1950, An annotated checklist and key to the reptiles of Mexico exclusive of the snakes. U.S. Nat. Mus. Bull. 199., p. 82) to distinguish *H. m. elegans* from *H. m. approximans.* Because *H. m. elegans* is not known to occur in the U.S., a positive allocation of the specimens to subspecies is not warranted.

I thank Dr. Hobart M. Smith for the photograph used in Figure 1. The sample has been deposited in the herpetological collection of the University of Colorado Museum (UCM 54206-54211).

Submitted by **HARRY L. TAYLOR,** Department of Biology, Regis College, Denver, Colorado 80221. ●

XANTUSIA RIVERSIANA (Island Night Lizard). **COLORATION.** *Xantusia riversiana* lives on only three islands off the coast of southern California (Santa Barbara, San Clemente and San Nicholas Islands). Bezy *et al.* (1980. pp. 565-583 *in:* The California Islands, Dennis M. Power, ed., Santa Barbara Mus. of Nat. Hist.) compared *X. riversiana* on all three islands with respect to electrophoretic differences, karyotypes, scalation, coloration, body size, clutch size, and variability. Color patterns in *X. riversiana* were described as highly variable including uniform, striped and mottled patterns. Bezy *et al.* noted that the mottled pattern occurs on all three islands while the striped pattern occurs on only San Clemente and San Nicholas Islands and the uniform pattern is present on only San Nicholas Island.

In the course of an ecological study on Santa Barbara Island, we have captured five lizards which had the striped pattern (Figure 1). These individuals represent 3.3% of the 154 lizards marked thus far. Perhaps this pattern was overlooked if, as suggested by Bezy *et al.,* the pattern is found only in local pockets.

Figure 1. Striped pattern of *Xantusia riversiana* on Santa Barbara Island.

SERPENTES

AGKISTRODON PISCIVORUS (Cottonmouth). **HYBRIDIZATION.** In an account of hybridization within Reptilia, Porter (1973. Herpetology, W. B. Sanders Co., Philadelphia) noted that "compared to the Amphibia, reptiles seem to hybridize very infrequently." He then proceeded to summarize the reported instances of hybridization between reptiles (P. 441). Among them were several involving crotaline snakes, including an intergeneric cross. He cited no records of hybridization between species of *Agkistrodon,* however, nor have we found any. Following is a general account of such an instance.

On October 14, 1979, the junior author noted copulation involving a male copperhead, *Agkistrodon contortrix,* and a female cottonmouth, *A. piscivorus,* in his possession. The snakes were in copula for at least 45 min. The copperhead was collected in Tallapoosa Co., Alabama, and the cottonmouth in Collier Co., Florida, where the incident took place. They had been in captivity together for approximately 3 years.

The cottonmouth gave birth to 6 young during the first week of the following August (1980). Examination of the neonates, all of which seemed perfectly healthy and normal, revealed their obviously hybrid nature. Measurements were not taken, but all were within the usual size ranges of neonatal *Agkistrodon.*

Two of the snakes refused to eat and ultimately died. The remaining 4 took mice and remained active and healthy until June, 1981. In early August, 1981, two more died, after a lengthy period of repeatedly regurgitating their food. The junior author, and amateur, was unaware of the importance of preserving the dead snakes and discarded them. Of the remaining two, one was presented to a physician in Gainesville, Florida and the other to the senior author. The latter (Fig. 1) is presently (1 June 1982) active, feeding well, and in apparent good health in the Auburn University Museum.

The snake's dorsum has 23 scale rows at midbody and is intermediate in color pattern, although it resembles that of a cottonmouth somewhat more than that of a copperhead. The shape and color of the head and the pattern on the belly more closely resemble those of a copperhead. The presence or absence of a loreal and other descriptive details must await a more thorough examination of the animal than that to which are willing to subject it as this time.

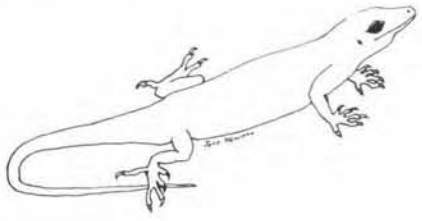

Figure 1. Hybrid between *Agkistrodon contortrix* (Tallapoosa Co., Alabama) and *A. piscivorus* (Collier Co., Florida) in the Auburn University Museum.

DIADOPHIS PUNCTATUS EDWARDSI (Northern Ringneck Snake). **SIZE.** A large *Diadophis punctatus edwardsi* was caught by Robert Spalding, Jr. on 7 May 1982 as it crossed a U. S. Forestry Service road in Cherokee National Forest, Monroe Co., Tennessee. The snake is a female with a total length of 706 mm (568 mm SVL, 138 mm TL).

The record length for *D. p. edwardsi* is reported as 625 mm by Conant (1975. A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co., Boston).

The snake is presently on loan to the Chattanooga Nature Center and is being maintained by John Muir, South Pittsburg, Tennessee.

MASTICOPHIS LATERALIS (California Striped Racer). **FOOD.** On 22 April 1973 at ca. 1015 hours, a specimen of *Masticophis lateralis* was observed eating an adult *Gerrhonotus multicarinatus.* The snake and lizard were in an oak-shaded ravine 0.5 km west of Carbon Canyon, Orange County, California. The lizard was approximately one third swallowed when the snake, apparently disturbed by my presence, disgorged it. The lizard immediately ran for shelter beneath the dense undergrowth. The snake was captured and measured (total length = 98.2 cm, with a portion of its tail missing).

A second specimen of *M. lateralis* was observed in direct sunlight on 2 July 1977 at 0945 hours, eating a subadult *Sceloporus orcutti.* Once again the snake disgorged the lizard as I approached, and both escaped. The latter observation occurred in Idyllwild County Park, Riverside County, California. Though *M. lateralis* is known to prey upon lizards (Klauber, Bull. Zool. Soc. San Diego 8:1-93, 1931; Stebbins, Amphibians and Reptiles of Western North America, McGraw Hill Book Co., New York, 536 pp., 1954), these are the first observations of these two lizard species as prey.

NAJA NAJA NAJA (Indian Cobra). **COLORATION.** Madras, So. India. While touring southern India in March, 1981, I had the fortunate experience of observing and photographing one of the rarest hood markings in cobras. An adult, *Naja naja naja* had been recently obtained by the Madras Snake Park, Madras, South India, and apparently was collected locally. Bob Larson (Hogle Zoo, Salt Lake City, Utah), at the time employed at the Snake Park, had noticed the unusual nature of the hood design and had isolated the specimen for further examination. The dorsal hood marking was similar to the description of Deraniyagala (1960, The Taxonomy of the Cobras of South Eastern Asia, Spol. Zeyl. Geol. Zool. Anthropol., 29:41-43) who described five types of dorsal hood markings in Asian cobras, and added an additional sixth type as follows: "An additional type of marking sometimes occurs between the back of the head and the main hood marking. This consists of a row of two to six white spots with dark margins *which might be connected* to form a transverse bar across the hood anterior to the two main ocelli of the spectacles marking. This is the color variety *polyocellata* Deraniyagala and such cobras only exist in Ceylon and Southern India." Plates III and IV in Deraniyagala's report illustrate various markings above the spectacle design in *Naja n. naja* specimens from Ceylon (Sri Lanka). He notes that approximately 20% of the Ceylon cobras exhibited markings in this hood region, which he terms a color variety *polyocellata* (not a subspecies). He further adds that this variety is rarer in Southern India than in Ceylon. Two small white spots in this hood region are also illustrated by Deoras (1971, The Story of Some Indian Poisonous Snakes. In: Venomous Animals and Their Venoms, Vol. II, Academic Press, N.Y., pp 41-63).

In this specimen, the white zig-zag design bordered by dark margins formed a twin-peak-like mountain scene, extending straight across the dorsal hood region approximately midway between the back of the head and the spectacle design (Figure 1a). The ventral view (Figure 1b) appeared normal, as did other body markings.

It is impossible to judge how common this hood design is in the region by quizzing the local Irula "snake catchers" or the local snake charmers ("magicians"). They show little interest in such matters and will often favor you with "what they think you want to hear." However, Romulus Whitaker, Director of the Madras Snake Park, is undoubtedly one of the most knowledgeable and experienced herpetologists in India. He has seen thousands of cobra skins in the markets, plus hundreds of live cobras from the region. He said this pattern was highly unusual and he had never noticed it before in his experience. He further noted, as did other Snake Park employees, that they had seen cobras with either black or white spots in this hood region, and this was fairly common.

Regardless of how unique this hood marking is, it represents one of the most ornate and attractive designs in cobra hood patterns. This information has been reported through the permission of the Madras Snake Park Trust, Deer Sanctuary, Guindy, Madras 600 022 India.

VIRGINIA VALERIAE (Smooth Earth Snake). **SIZE.** On 13 April, 1982, an exceptionally large *Virginia valeriae elegans* was collected by Nicholas A. Laposha and Kenneth P. Bromeier in the Blue River valley, Kansas City, Jackson County, Missouri. The animal is a female with a total length of 393mm (342mm SVL, 51mm TL). The specimen has been deposited in the Bobby Witcher Memorial Collection (BWMC 01714) at Avila College, Kansas City.

The record length reported for the species by Conant (1975. A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co., Boston) was 338mm. The previous record for Missouri was 285mm, reported by Anderson (1965. The reptiles of Missouri, Univ. Mo. Press, Columbia). Collins (1974. Amphibians and reptiles in Kansas, Univ. Ks. Mus. Nat. Hist. Publ. Educ. Ser. No. 1, Lawrence) reported in Kansas record of 327mm from Wyandotte County (immediately west of Jackson County, Missouri), and noted that that record apparently represented the maximum size for the species at that time. The specimen reported herein surpasses by 56mm the record reported by Conant and by 66mm that reported by Collins, thereby representing a new record length for the species.

TESTUDINES

GEOCHELONE ELEGANS (Indian Star Tortoise). **FECUNDITY.** Deraniyagala (1939, The Tetrapod Reptiles of Ceylon, Vol. 1) reported for *Geochelone elegans* in Sri Lanka that, "Three to six eggs are laid at a time and two or three batches appear to be laid annually, for specimens dissected after oviposition contain half developed eggs" (p.287). Jayakar and Spurway (1966, J. Bombay Nat. Hist. Soc. 63 (1):83-114) reported a clutch of seven eggs laid on 18 April 1964 in Bhubaneswar. Four additional eggs found later, were laid by the same female, but in a different nest. However these authors concluded, "It is not impossible that these 11 eggs were all laid on 18/iv/64 before midnight" (p.89).

A female *G. elegans* of unknown origin, in captivity since 20 April 1968, laid nine clutches during the period 5 June 1977 to 17 October 1980. The clutch sizes, in chronological order, were 5, 5, 6, 7, 5, 9, 10, 5, and 8 eggs. The clutch of 10 eggs was laid on 14 May 1980. The first eight clutches were the result of mating with the same male. All 52 eggs from those clutches were infertile. The last clutch (eight eggs) was the result of mating with one or more of a group of three males while the female *G. elegans* was on a breeding loan. Coakley (1981, J. NOAH 7 (1):1-6) reported three hatchlings from that clutch. Incubation periods were 111, 113, and 127 days. All three hatchlings were still alive at the time this paper was submitted (7 June 1982).

In the calendar years 1977 through 1980, three was the maximum number of clutches laid annually (1977, 1980) and 23 was the maximum number of eggs laid annually (1980). If the term, "annually", is taken to mean a 12 month period other than a calendar year, then four was the maximum number of clutches laid (5 June 1977 through 27 May 1978) and 23 was again the maximum number of eggs laid (same period).

TECHNIQUES

NEW METHODS FOR MEASURING AND TAGGING SNAKES

The need for an accurate and harmless technique for measuring the length of snakes is long-standing and reflected in the results of several studies including those of Fitch and Glading, 1947, Fitch, 1949, and Wharton, 1966. Such studies report fluctuations in recapture lengths and/or loss of body weight, indicating inaccuracy and injury to the snake, respectively. Concern has been expressed by workers that rough handling of the snakes was a major cause of the problem. These problems can be avoided by either of two alternative methods for measuring live snakes of any size, both tested in a field study of *Sistrurus miliarius* (Serpentes: Crotalidae) in south Florida (Hudnall, 1979).

Photographed Snake Measurement. The procedure is as follows: 1. The snake, a meter stick, and an appropriate identification card are photographed from directly above using slide film. 2. The slide is projected onto a piece of paper and the snake's outline is traced along with an increment of the meter stick for scale. 3. The snake's length is then obtained with a measuring wheel (a Germany brand device was used) commonly used in reading map mileages, and comparing it with the meter stick increment. If the snout-vent length is desired, a water base paint can be applied to the back above the vent before photographing.

Accuracy in this method was determined by photographing two *S. miliarius*, one six times and the other seven times, disturbing the snakes between each photograph to assess the effect of different body positions on the measured length; this work was done in a field enclosure. The photographed measurements (N = 13) differed from each other by 4.5-6.1% of the smallest photographed-measured length. These same photographed measurements were within 0.3-3.4% of direct measurements of the chilled snakes (method below).

The great advantages of this method for field studies include simple, portable equipment (camera, film, and ruler), and that it features universal applicability to all reptiles and amphibians in that the animals are not manipulated mechanically or physiologically. The time investment (excluding film development, ca. 15 minutes per snake) could be limiting for processing especially large numbers of snakes.

Chilled Snake Measurement. — The procedure is as follows: 1. The snake is placed in a jar with enough water to cover it, and the jar is placed in an ice-water mixture. 2. When the temperature of the jar approaches 5 C, either submerge the snake directly into the ice-water mixture or add ice to the jar to finish chilling it. 3. The snake can then be readily straightened out along a meter stick for measuring. 4. The snake is placed in a shaded area for a short period to allow gradual re-warming.

The time required for chilling will differ with the size of the snake to be measured. This technique was used on pigmy rattlesnakes *(Sistrurus miliarius)* in southern Florida. Their weights ranged from 17 to 70 grams, and it was found that 15-20 minutes at step 1, with an additional 3-5 minutes at step 2 was sufficient to immobilize them.

Possible inconsistency in this method was checked. Three *S. miliarius* and one *Agkistrodon piscivorus* were chilled five times each over a ten day period. They measured from 453 mm to 523 mm in length; the measurements differed by less than one per cent (0.65-0.96%) of their total length.

Of 22 recaptures of *S. miliarius* in a field marking study using this method, 63.6% gained and 36.4% lost weight over periods from 7 to 294 days. Further, six *S. miliarius* were chilled and measured in the lab; all ate readily the following day and did well during a seven month observation period. This indicates that the chilling process as employed was not harmful to these snakes. However, it is strongly recommended that different species be tested in the lab prior to using this method in the field; some species may succumb to the severe change in body temperature (see Heatwole *et al.*, 1969 and Lowe *et al.*, 1971).

Color-bead Tagging Method. — This method employs monofilament suture-line mounted on a surgical needle, available from surgical supply houses, to attach two or more colored glass beads to a snake's tail. The glass beads, commonly used in decorations on belts and handbags, can be obtained in a variety of colors from hobby stores.

The procedure is as follows: 1. A bead is threaded onto the line and a knot is tied in the end of it. 2. The needle is inserted into the snake's tail dorso-laterally and run along the backbone for at least 13 mm. 3. The slack is pulled through the tail so that the bead is snug against the skin. 4. The line is clipped far enough from the skin to allow room for tying another knot after a bead has been threaded onto it. The beads should be tied close to the skin to reduce snagging on brush while the snake is moving. The process requires three to four minutes per snake. Individual snakes are distinguished by the color sequence of the beads and the color of the line (Fig. 1).

In a long-term field project of *S. miliarius* in southern Florida (Hudnall, 1979) it was found that the bead tag had a tendency to pull free after several skin sheds, leaving a detectable scar. This was probably due to the small diameter of the tail which afforded little musculature to resist the pulling of the tag. This tag will last even longer on larger snakes.

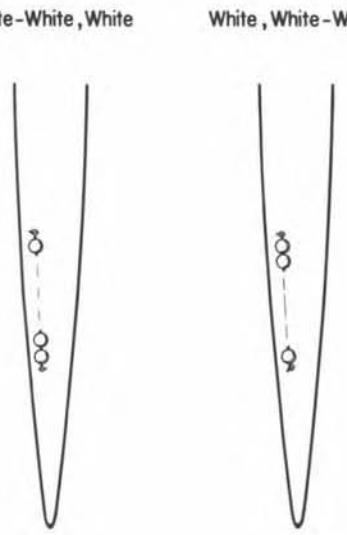

Figure 1. Diagrammatic dorsal view of snake tails tagged with three white beads in two arrangements; dashed line indicates subcutaneous position of monofilament suture-line.

The small size of the pigmy rattlesnake tail precluded successful use of the Buttoneer marking method (Pough, 1970). As Pough and others have noted, the Buttoneer method is applicable to snakes 250 mm or more in total length. The bead tagging method, unlike the Buttoneer and other tagging methods in the literature (see Ferner, 1979), is useful on snakes as small as 180 mm.

In situations where small snakes (< 250 mm) are tagged, a short-term tag is desired, and/or the need for remote identification presents itself, this method is satisfactory. With binoculars, individuals are easily identified at considerable distance. Application of the tag causes no apparent distress to the snake; of 50 tagged *S. miliarius*, 16 (=32%) were recaptured after periods of up to one year and none showed any signs of infection or impediment of movement at any time. This recapture success in a very brushy study area strongly suggests mortality was not increased with this tagging method.

ACKNOWLEDGMENTS

I thank my father, Jack L. Hudnall, for his open and enthusiastic exchange of ideas in the development and testing of these techniques, as well as his moral, financial, and technical support during this study. I especially thank Dr. Charles Lowe, University of Arizona, for kindly and critically reviewing this manuscript, and for providing moral and financial support throughout its preparation.

BOOK REVIEWS

Biomechanics. An approach to vertebrate biology. by Carl Gans. 1974. J. B. Lippincott Company, New York. x + 261 pp. Available for $6.50 postpaid from: University of Michigan Press, P.O. Box 104, Ann Arbor, Michigan 48106.

This is an unusual book. Most herpetologists might overlook it and its relevance to amphibian and reptilian biology — its title obscures the wealth of herpetological information and the philosophy that Gans brings to the study of lower vertebrates. Herpetological literature is replete with extensive taxonomic, regional, and demographic tomes, and, with the exception of a few herpetology texts and Gans' "Biology of the Reptilia" (1969 *et seq.*), few books which adopt a different view of amphibians and reptiles have appeared in recent years.

"Biomechanics" is a five-chapter book about functional morphology which draws almost exclusively on amphibians and reptiles as examples for analysis. Its first chapter defines structures and adaptations, presents a model for analysis, and closes with a rationale for comparison which concludes that "actual observation rather than extrapolation, living specimens rather than preserved materials, manipulation rather than passive observation of the system, and comparison rather than conclusions from single forms represent optimal approaches to the study of biomechanics." The following four chapters deal with analytical approaches to diverse problems involving structure and adaptation.

Chapter 2 is an analysis of structure using dissection and observation of egg-eating snakes, with emphasis on the genus *Dasypeltis*. Chapter 3 is an investigation of locomotion without limbs and features the adaptations of snakes, concluding with a brief discussion of lateral undulation and its significance to the phylogeny of vertebrates. This third chapter is an illustration of analysis by limiting the question. Chapter 4 is a discussion of analysis by comparison using the burrowing habits of amphisbaenians as examples of structural adaptation. The final chapter is a description of analysis by quantification using as an example air breathing and vocalization in frogs, and featuring electromyographical analysis, an experimental technique that Gans has explored and utilized more extensively since this book appeared.

This book is cohesive and easily read with profit by herpetologists from zoos, museums, and universities, and particularly by the large numbers of herpetologists who maintain amphibians and reptiles as an avocation. Gans states that this book is "intensely personal," and he restricts amphibian and reptilian examples used in the book to those forms with which he has experimented personally. His intent to present examples of analyses in functional morphology, to offer samples of approaches to functional morphology and samples of philosophy from which the approaches derive has been achieved. In addition, he has admirably presented a little-used approach which herpetological systematists and physiologists might embrace in their future research.

JOSEPH T. COLLINS
Museum of Natural History
University of Kansas

Synopsis of the Herpetofauna of Mexico, Volume VI. Guide to Mexican Turtles and Bibliographic Addendum III, by Hobart M. Smith and Rozella B. Smith. 1980, 1044 pages. $40.00. John Johnson Natural History Books, North Bennington, Vermont.

This book represents the sixth volume in the Smith's monumental series on the amphibians and reptiles of Mexico. The main text is totally devoted to turtles, but also included is a general literature addendum to the previous volumes.

The Preface explains the significance, objectives, and status of the entire series project; and the organization of the present volume is briefly outlined. The objectives of this volume being to provide as complete a survey of the present knowledge of the turtle fauna of Mexico as possible, in as practically usable a form as possible.

The Introduction summarizes the turtle fauna of Mexico, 60 species and subspecies, and compares it with that of the United States and Canada. This is followed by a brief description of some taxonomic problems relating to Mexican turtles, the sources of the data included, acknowledgements, a list of acronyms of the 70 scientific collections containing Mexican turtles, and explanations of the literature citations and map preparations.

A section entitled Systematic Accounts appears next and includes the synonomies, nomenclatural history, and definitions of the

higher taxonomy of Mexican turtles: Subclass Chelonomorpha, Order Testudines, Suborder Casichelydia, Infraorder Cryptodira, and Parvorder Eucryptodira. In this respect it is refreshing to find that the authors have used the modern classification proposed by Gaffney (1975). Adequate keys are then provided to the families, genera, and species. In some cases these keys were prepared by known experts on the taxon. Each superfamily, family, subfamily, tribe, subtribe, and genus is fully described and its synonomy, nomenclatural history and geographical range is given.

The accounts of each species include a fully referenced synonomy, a nomenclatural history, a discussion of its taxonomic status, and a listing of the pertinent literature involving the species. For each reference, an index number is listed which refers to a bibliographic entry in either the Addendum in this book or to one of the previous volumes of the series. The literature section is subdivided into such topics as popular books, ecology, zoo breeding, regional accounts, anatomy, physiology, parasitology, paleontology, and taxonomy. A well organized, detailed description is included for each species, and its general range and etymology are discussed. For those species with recognized subspecies, a key to the Mexican subspecies follows, and then each subspecies is described and discussed in detail in a similar format as that of the entire species. The range of each subspecies is given, and a list of Mexican localities is presented. Another feature of each subspecific account is its conservational status in which harmful practices or situations are discussed and suggested methods of protection given. Mexican range maps for each taxon are included near the end of the book, as also are drawings or black and white photographs of most.

A detailed Gazetteer gives, in alphabetical order, all Mexican localities from which turtles have been recorded. The quadrant and state in which the locality is found, and all of the species and subspecies of turtles recorded from it are also given. Finally, a cross-index to secondary localities of particular importance for reference to rivers, follows the main list of localities.

The Bibliographic Addendum III is a list of 767 titles pertinent to Mexican herpetology not included in the earlier volumes of the series. Many are pertinent to the turtles and are indexed and cited by entry number in the taxonomic accounts of the text. All entries in the Addendum bear distinctive numbers integrated with, but not duplicated by those of the preceding volumes.

The book ends with adequate indexes to the subject matter and scientific names.

The text is written in both an interesting and informative manner, with few spelling or typographical errors. The binding seems adequate, but the printing is small and somewhat light. The illustrations, many reprinted with permission from the works of others, are often of poor quality, too dark, or too small to adequately show the important features.

There are few errors in the taxon descriptions and keys. For instance, in the key to the subspecies of *Rhinoclemmys pulcherrima, rogerbarbouri* and *incisa* are separated on the basis of the extent of the dark plastral figure when, in reality, this is very similar and overlaps greatly.

The text is perhaps slanted too much toward taxonomy, but this is the Smiths' major interest. The use of two nomenclatural combinations may cause come confusion and consternation among chelonian systematists — *Trionyx spiniferus asper* and *Caretta caretta tarapacana*. The former is usually considered a full species, while the eastern Pacific loggerheads are more commonly known as *Caretta c. gigas* and the name *tarapacana* is unfamiliar to most herpetologists. In each case, the authors have documented their reasons for the use of these names.

The Major criticism of this book, however, is one which is inherent to the series as a whole. The reader needs either to own or have readily available the other volumes of the series in order to find all of the numerically listed references. On an individual basis this becomes expensive; however, the libraries of most universities and museums now subscribe to the series, and it is more locally available than before.

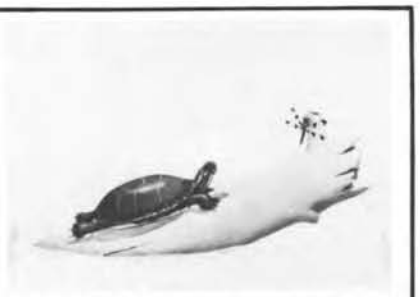
Despite these few problems, the book is an excellent source of information on Mexican turtles, and is a necessary reference for all who plan to study the Mexican herpetofauna. Much more data is to be found between its covers than could be adequately described in the short space of this review. It is a highly recommended volume for all herpetologists and biological libraries.

LITERATURE CITED

Gaffney, E. S. 1975. A phylogeny and classification of the higher categories of turtles. Bull. Amer. Mus. Natur. Hist. 155(5): 387-436.

CARL H. ERNST
George Mason University

South African Frogs, by Passmore, N. I. and V. C. Carruthers. 1979. Witwatersrand University Press, Johannesburg. xviii + 270pp., ill. + Voices of South African Frogs.



This publication represents not only a beautiful book, worthy of the coffee table trade, but also one useful to the more scientifically inclined herpetologist. As suggested in Foreword by Prof. Paterson, it should certainly stimulate interest in South African frogs and help motivate studies on a relatively poorly-known segment of the fauna.

There are 10 short introductory chapters dealing with frogs and frog biology, including an important discussion on frog sounds. Considerable weight is placed on frog vocalizations as being an important component of specific mate recognition systems. Sonagrams accompany each species description and a 7-inch two-sided 33.3 record is included as a supplement. The reader is urged to study the sonagrams in conjunction with listening to the record.

Eighty-four species comprise the anuran fauna of South Africa and each is illustrated by a color photograph of superb artistry, a distribution map, a sonogram, plus a number of black and white photographs illustrating the salient morphological features that distinguish any given species from its nearest relatives. Color variation, which is considerable in many of the species, is emphasized by showing several selections from the range of colors and patterns. Subspecies are treated in a reasonable fashion, shown in color plates, but described in more detail in an appendix. One feature that is puzzling to me — each species has a black and white photo purporting to represent life size. If these dimensions are accurate, then the frog fauna of South Africa must be composed of midgets. I know that *Xenopus* and *Pyxicephalus* grow larger than the illustrations depict — do the others? Unfortunately, tadpoles are neither illustrated nor described in any significant way so only metamorphosed individuals can be truly identified. A selected bibliography, an index, and a glossary of sorts complete the text.

This is an excellent book both for its contents and for its printing.

Ohio University, Athens

NATURE PRINTS
BY DAVID M. DENNIS

We are pleased to offer exquisite, full-color art prints by David M. Dennis, naturalist and professional scientific illustrator renown for his watercolors of unusual wildlife. First set of 4 now available: Green frog, Painted turtle, Spotted salamanders, Beetle and Red salamander. Prints measure 20 × 24 inches, each signed and numbered by Mr. Dennis in editions limited to only 500. $25 each or $85 set of 4, plus shipping ($4.50) and any NY taxes. Send orders to Biographics, 12 Eagle's Head Rd., Ithaca, NY 14850. Illustrated brochure on request.

Turtles: Perspectives and Research. Edited by Marion Harless and Henry Morlock. 1979. John Wiley & Sons, New York. 695 p.

Like its subject, this book is at once ponderous and graceful. The chapters mix much original material with analyses of the literature (through the early 1970s). The opening chapter on taxonomy and distribution (P. C. H. Pritchard) is concise and readable.

A practical manual of methods is next: capture, marking (M. V. Plummer); telemetry (W. K. Legler); life history techniques (T. E. Graham); photographic analysis of behavior (C. C. Carpenter); lab maintenance (H. W. Campbell, S. D. Busack); anesthesia, surgery (J. H. Maxwell). The material is clear but occasionally oversimplified. For example, I have found some turtles *(Chelydra, Terrapene)* more difficult to sex than implied on p. 82-83. Potential impacts of study techniques need more attention (*e.g.*, radioactive tags, anesthetics, pesticides for parasitic arthropods, confinement in small cages). Suppliers' addresses are given in one chapter and would have been useful in others.

The section on vital functions covers: cardiovascular system (C. G. Jackson); respiration (D. C. Jackson); brain (A. S. Powers, A. J. Reiner); thermoregulation (V. H. Hutchison); feeding, drinking, excretion (I. Y. Mahmoud, J. Klicka). I enjoyed most the elucidation of unique breathing and buoyancy control mechanisms. Some chapters need more graphics.

Selected senses are the subjects of: eyes and color sensitivity (A. M. Granda); smell and taste (T. R. Scott); olfactory behavior (M. L. Manton). "There is no concrete evidence that olfaction is critical in any of the life functions of turtles" (p. 289), but how do some species feed and orient in very turbid waters?

Reproductive cycles and adaptations (E. O. Moll) and the embryo and its egg (M. A. Ewert) make up the section on reproduction and development. Ewert has assembled data on egg and hatchling measurements, eggshell characteristics, egg constituents, incubation periods, and 29 good black-and-white photos of terata into a fascinating and perceptive mini-book.

A section on behavior includes: (D. W. Ehrenfeld); locomotion (W. F. Walker); learning (H. Morlock); social behavior (M. Harless); emotional reactivity (I. M. Spiegel); rhythms (E. V. Gourley). Ehrenfeld analyzes activities from landfall to re-entry into the water, with a final stimulating discussion of orientation. Harless includes intriguing observations on *Clemmys insculpta* in an outdoor pen. Spiegel treats the effects of drugs, cerebral lesions, and various stimuli on *Chrysemys picta* behavior in experimental apparatus, with little evident awareness of wild behavior. However, the use of excretory sodium and potassium levels in cage water as indicators of emotional status is a very promising technique.

The book concludes with discussions of population ecology of sea (H. R. Bustard), land (W. Auffenberg, J. B. Iverson), and freshwater turtles (R. B. Bury). Sea turtle "farming" is proposed as a cottage industry to give Third World consumers a stake in resource stewardship, and *Gopherus polyphemus* populations are related to vegetation variation in space and time.

This book should stimulate lab and field workers to collaborate in testing and amplifying proposed techniques and hypotheses. There is much to be learned, with a minimum of potentially behavior-distorting or inhumane drugs, surgery and hardware necessary. Biologists could: choose research projects with clear application to conservation problems, and use these problems to approach "pure science" questions; and obtain their experimental animals from captive-bred or reared stocks, or collect them from the wild while observing behavior and monitoring population size.

Most of the authors do not provide recommendations to implement the editors' desire for conservation of wild populations. Bury concludes that "information on the population ecology of freshwater turtles is wholly inadequate for conservation and management of these resources". Lack of comparative natural history data as basic as nest chamber dimensions is mentioned several times (here is work for careful amateurs and students). Graham warns that field studies are often halted by land development projects; but are parks and sanctuaries always safe from dumps, impoundments, parking lots?

Some potentially misleading errors are: "Atland" for Altland (p. 60); "mm/sec" for frames/sec (99); "miasis" for myiasis (124); "*Chrysemys picta*" for *Pseudemys scripta* (214); "Friar" for Frair (226, 234); "concostracod" for conchostracan or ostracod (232); "orinithine" for ornithine (240); "Risely" for Risley (390); "rigor" for vigor (392); "*typhinurium*" for *typhimurium* (399); "external" for internal (402); "*Malaclemmys*" for *Malaclemys* (516); "arribidas" for arribadas (525); and "Tonier" for Toner (572). The photos are switched on p. 329-330. Fig. 1a (437) shows right lateral and ventral (not "dorsal") views. *Chelydra* matures at 200 mm carapace (not plastron) length, equivalent to 145 mm plastron length (578). Some abbreviations in the figures on p. 196-201 suffer from reduction. In my copy, p. 321-328 are badly wrinkled.

More integration among chapters, and addition of non-technical abstracts would improve a 2nd edition. I would like to see a photo of a wild turtle rather than a specimen on the dust jacket. And the publisher should consider selling paperbound separates of the sections to people who can't spend $45 for the whole book.

SSAR SILVER ANNIVERSARY COMMEMORATIVE PRINT

SSAR SILVER ANNIVERSARY COMMEMORATIVE PRINT

As part of the 25th Anniversary Celebration the Society has issued a beautiful *full-color* print of a Gila monster, taken from a watercolor drawing by the noted wildlife artist David M. Dennis. The print measures 11½ by 15¼ inches (29 by 38.5 cm) and is printed on a very heavy acid-free paper stock so that it can be framed or used as a poster.

The edition is strictly limited to 1000 copies, most of which were distributed at the Annual Meeting in Raleigh in August, but some copies remain for sale on a first-come, first-served basis. Prices are $10 each postpaid, or $8 each in quantities of 10 or more. Send orders to Dr. Douglas H. Taylor, SSAR Publications Secretary, Department of Zoology, Miami University, Oxford, Ohio 45056, U.S.A. Checks should be made payable to "SSAR"; payment in U.S. funds, please. ●

HERPETOLOGISTS' LEAGUE

HERPETOLOGISTS' LEAGUE (HL) is an international, non-profit organization of professional and amateur herpetologists, founded in 1936 by Chapman Grant, and dedicated to furthering knowledge of the biology of amphibians and reptiles. The League publishes a scholarly journal, *Herpetologica*, which appears quarterly, and a *Herpetological Monograph Series*, issues of which appear irregularly. All members in good standing receive *Herpetologica*.

The League holds its annual meeting, usually in August, in conjunction with the Society for the Study of Amphibians and Reptiles. Symposia, contributed papers, poster sessions, various displays, and the HL Distinguished Herpetologist's Lecture facilitate the exchange of information and ideas on a wide array of herpetological topics. Prizes are awarded for the best student paper and best student poster presented at the meeting.

Membership in THE HERPETOLOGISTS' LEAGUE is open to anyone with an interest in the biology of amphibians and/or reptiles. New members are welcomed and are encouraged to participate in League affairs. Application for membership should be made to the Treasurer, Laurence M. Hardy, Department of Biological Sciences, Louisiana State University in Shreveport, 8515 Youree Drive, Shreveport, Louisiana 71115 USA. Annual dues are $15.00 for individuals and $17.00 for family membership. Subscriptions for institutions and nonmembers are $20.00 per annum. Make checks payable in U.S. funds to THE HERPETOLOGISTS' LEAGUE. Overseas subscribers who desire airmail delivery of the journal, add $12.00. Information on availability and cost of back issues of *Herpetologica* and the twenty year index can be obtained from the Publications Secretary, W. Ronald Heyer, Smithsonian Institution, Natural History Building, Washington, D.C. 20560. Additional information concerning membership, societal activities, and related matters can be obtained from the Secretary, Julian C. Lee, Department of Biology, University of Miami, P.O. Box 249118, Coral Gables, Florida 33124. ●

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the editor.

A WATERDOG BY ANY OTHER NAME IS NOT SO NEAT

The In-Fisherman, a "journal of freshwater fishing" that claims to have a large influence on the angling community, recently carried an article by its editor extolling the virtues of "waterdogs" as bait (Stange, D. 1982. The In-Fisherman 42:78-80, 81, 84, 81). The term "waterdog" is used in reference to gilled aquatic salamander larvae, in particular to tiger salamanders, *Ambystoma tigrinum.* In addition to this feature article, salamanders are promoted elsewhere in the same issue (pp. 50, 72, 181, 182, and the cover illustration, captioned "The waterdog breakthrough"). Although the use of salamanders as bait is nothing new, and although most herpetologists would probably be happy to find more than an academic interest in an object of their study, there are a number of disturbing elements about the current trend as described by *The Jn-Fisherman.*

First, indiscriminate use of the term "waterdog" (and "mudpuppy" on p. 79) will only increase the frequent confusion of ambystomid larvae with *Necturus,* especially when this use is propagated by an author who claims to have been a former high school biology teacher. To add to this confusion, illustrations of "waterdogs" on pp. 181, 182, and the cover depict four toes on each hind foot; five toes are clearly visible in the photographs on pp. 78-80.

Of far greater concern, however, are advertisements on pp. 141 and 144 offering "waterdogs" for sale, including an offer to ship the larvae anywhere in the U.S. or Canada except Saskatchewan. According to the feature article by Stange, these tiger salamanders have been selectively bred to produce a stock which is easy to maintain in the larval stage. There are many cases of bait species (*e.g.,* minnows and crayfish) becoming established outside their native ranges through release by well-meaning anglers who did not wish to kill their extra bait or by individuals who wished to establish their own naturally-breeding supply. Not only does this obfuscate original distribution patterns and frustrate zoogeographers, but it may have a negative impact on native species or conspecific stocks. The exotic crayfish *Orconectes rusticus,* for example, has replaced native crayfish in some northern Wisconsin lakes and has a serious impact on aquatic macrophyte beds (Lorman, J. G. 1980. Ecology of the crayfish *Orconectes rusticus* in northern Wisconsin. Ph.D. thesis, Univ. Wisconsin, Madison). *Ambystoma tigrinum* has already become established in several areas through bait release (Smith and Kohler. 1978. Trans. Kansas Acad. Sci. 80:1-24); commercial traffic can only aggravate the situation, as will the use of special hooks that do not injure the larvae to which they are attached and which thereby promote their survival (p. 72 of *The In-Fisherman*). The potential for genetic swamping of local stocks by commercially supplied salamanders is of particular concern in light of recent speculation that *Ambystoma tigrinum* may constitute a multi-species complex (Collins *et al.* 1980. Copeia 1980:938-941). Herpetologists should be aware of the possibilities and should support any state laws which limit the transportation, use, or release of exotic baits.

Anonymous

EDITOR'S NOTE: Several examples of such *Ambystoma* have been kept at K.U. as lab pets. They were on their way to being released in a local pond when I intercepted them. They were easy to maintain and eventually metamorphosed into what externally appears intermediate between *A. t. tigrinum* and *A. t. mavortium.* I do not know the supplier of stocks sold in Lawrence. **G.R.P.** ●

LETTER

LEGISLATIVE CHANGES NEEDED TO ENSURE SPECIES SURVIVAL

The recent "Snakescam" operation undertaken by the U.S. Fish and Wildlife Service has been the center of much controversy. The operation has brought the problems of wildlife protection laws into sharp focus. The abuse of civil rights which reportedly occurred cannot and should not be tolerated. Heretofore elusive effects of wildlife laws, regulations, and enforcement modes have emerged as very real and direct threats; not only to rare animals but also to the people who work with protected species. These laws discourage, rather than promote, activities such as captive propagation that are beneficial to wildlife. Research and breeding of protected species, especially by private parties, is effectively being legislated out of existence. Thus, we are being forced either to take action against the very department created to protect wildlife, or face systematic elimination of captive breeding, research, and our attendant civil rights. New legislation needs to be introduced; legislation which will encourage and assist activities beneficial to wildlife. Action towards this end can be on an individual and a group level.

Individual Action:

The "Snakescam" operation should be used to capture public attention. It is necessary to expose the violations of our civil rights and the harassment, coercion, and threats purportedly made by federal personnel. The fact that defendants are apparently being forced to prove their innocence, rather than being presumed innocent until proven guilty, is something that threatens the constitutional fabric of this country.

Concerned individuals must voice their opinions to their representatives! Some of us have already done this and the results are encouraging. Fish and Wildlife actions are being questioned in many areas. Demands for explanations have been issued by Senators and Congressmen. The more people who express themselves the more pressure will be brought to bear. Of especial value will be the testimony of those directly involved in the "Snakescam," as they can document unethical and illegal methods used. Too many persons are not making themselves heard for fear of further harassments. No changes will be made by sticking our heads in the sand! Unless we speak up now it will be nearly impossible to continue captive breeding, and the future of wildlife research will be jeopardized. The abuse of civil rights could set a precedent which will threaten other areas of scientific inquiry. Opinions need to be expressed to those who can make changes —our Senators, Congressmen, and the media.

Group Action:

There are four areas the various zoological societies across the country should address.

I. A committee is needed to draw up proposed amendments to the laws we are concerned with. These are the Endangered Species Act, the Lacey Act, the Migratory Bird Treaty, and the Convention on International Trade in Endangered Species (CITES). These amendments should stipulate that there be *no* restrictions on the sale, trade, transport, importation, exportation, or possession of any *captive born* wildlife. Protected animals now in captivity in the United States should be granted a general amnesty. This is necessary because proof of legal origin is often impossible for animals acquired prior to their protection, as well as animals collected from areas where they are not protected. A general amnesty would remove the necessity for proving legal origins for animals already in captivity. It would stimulate persons with animals of undetermined origins to bring these animals into breeding situations. An attitude of encouraging and assisting captive breeding and other activities beneficial to wildlife should be an underlying basis of wildlife laws. They should not be just a negative set of restrictions and prohibitions. They should take an actively positive approach by promoting captive breeding, as well as animal product farms that benefit wildlife by providing legal sources for animal products.

The October 1982 reauthorization of the Endangered Species Act is an ideal time to introduce an amendment. A means of changing the other laws should be formed. This effort will require a legal team, and it may be desirable to work in cooperation with a national wildlife organization. The need for these amendments must be brought to the attention of our legislators. Individuals and wildlife organizations need to express their concern for making these changes to their representatives.

II. Zoological societies should issue demands for action to their representatives. The opinion of a society representing many people carries weight in political considerations. Zoological societies should use this power to the best advantage.

III. Individuals and zoological societies should approach other wildlife organizations. These groups cannot help but be concerned over the destruction of research and wildlife that has occurred, as well as the problems of captive propagation. The situation we are facing should be brought to the attention of these groups.

Traditionally, most wildlife organizations have supported prohibitions on live trade.

These laws have been portrayed as essential for wildlife protection. However, it can be documented that many of these laws and regulations pose a threat to captive wildlife. Regulations that apply to captive wildlife are compelling zoos, researchers, and private individuals *not* to breed rare and endangered animals in their collections. Further, the attitudes and enforcement activities of the Fish and Wildlife Service have created an unprecedented paranoia among zoological personnel throughout the United States! The inability to obtain permits to move offspring or acquire mates for lone animals can be documented, as well as unreasonably long waiting periods for permits. In this time of rapid habitat loss, more and more species are becoming dependent on captive propagation for their very survival. Yet, our laws consist mainly of a negative set of restrictions and prohibitions that discourage the breeding of rare animals.

IV. Foreign zoos and wildlife concerns should also be approached. They can put pressure on the United States to allow free trade in captive born wildlife for breeding purposes. Many zoos have been frustrated by an inability to obtain mates for rare animals from overseas. This frustration works both ways.

SUMMARY

This note is a plan of action extracted from a lengthy proposal illustrating the problems with current wildlife laws. The restrictions which make captive breeding of rare and endangered species nearly impossible are discussed. The recent "Snakescam" operation undertaken by the U.S. Fish and Wildlife Service exemplifies this dilemma. Laws and regulations now in effect are basically a set of restrictions and prohibitions, which discourage, rather than promote, activities such as captive breeding which are beneficial to wildlife. Wildlife agencies should promote, aid, and cooperate with public and private efforts to propagate rare species. Encouragement should be given to animal product farms, which relieve pressure on wild populations by providing a legal source for superior quality products. Rewriting laws to achieve this would have many benefits for wildlife.

A plan of action for implementing this ideal includes:

I. Amendments to the Endangered Species Act, Lacey Act, Migratory Bird Treaty, and CITES Treaty. These amendments should include:
   - A) No restrictions on the sale, trade, transport, importation, exportation, or possession of any captive born wildlife.
   - B) A general amnesty for animals now in captivity.
   - C) Requirements for wildlife agencies to encourage and assist captive and semi-captive breeding programs, public and private.
   - D) Provisions to ensure the employment of teams of expert personnel (public and private) when establishing regulations on trade in live fauna, and all other policies regarding wildlife.
   - E) Incentives for animal farms which will provide legal sources for animal products, take pressure off wild populations, and make it uneconomical for poachers and illegal suppliers to operate.

II. Concerned individuals should express their opinions to their representatives.

III. Zoological societies should issue demands for action to their representatives.

IV. The problems with current wildlife laws should be brought to the attention of national wildlife organizations and foreign concerns. These groups should be requested to express their concerns to our legislators and to aid in revising laws and regulations.

V. Our legislators should be convinced of the need to change wildlife laws. Zoological societies, wildlife groups, and concerned individuals should work with our legislators to introduce amendments to these laws.

The inequities of the "Snakescam" operation are currently being investigated and documented by the author. The full version of this proposal, detailing problems with current wildlife laws and the benefits of revision, is being reworked and documented for publication. Anyone interested in learning more about this situation or wishing to contribute ideas should contact the author at the address below. Any and all comments are welcome.

Herpetological Circulars Seeks Manuscripts

As of 1983, I will be taking over the editorship of **Herpetological Circulars** from the capable hands of Joseph Collins. I hope to continue the outstanding style and success of previous issues of this publication. To that effect, I would like to solicit appropriate manuscripts from prospective authors. These manuscripts should be of intermediate length (20 to 100 pages, typed, double spaced) on subjects of general interest to herpetologists. Past topics have varied from animal husbandry to historical reviews of herpetology. If you have such a manuscript or ideas for one that might be appropriate, please contact me.

ABSENCE OF *STAPHYLOCOCCUS AUREUS* IN THE ORAL CAVITIES OF CAPTIVE HARMLESS SNAKES

Recently a case of wound infection following the bite of a harmless snake was related to me by a physician. This infection could easily have been caused by bacteria present on the person's skin or by later contamination of the bite wound. However, bacteria from the snake's oral cavity could also have caused the infection and thus it seemed meaningful to investigate their occurrence.

A preliminary study to determine the common morphologic types of oral bacteria (which would grow at human body temperature) present in harmless snakes was first conducted. Three captive snakes were sampled — eastern king snake *(Lampropeltis getulus getulus)*, black rat snake *(Elaphe obsoleta obsoleta)*, eastern garter snake *(Thamnophis sirtalis sirtalis)*. The oral cavity of each was sampled with a sterile cotton swab. Two blood agar plates for each sample were then streaked and incubated aerobically at 37° C for 24 hr. Colonies of the various cultural types were subcultured in tryptic soy broth and incubated as before. Gram stains of each culture were examined. Gram negative bacilli (40 cultures), Gram positive staphylococci (20 cultures), and Gram negative diplococci (5 cultures) were observed.

Since *Staphylococcus aureus* is sometimes implicated in wound infections (Bauer, *et al.*, 1974) and has been isolated from the oral cavities of venomous snakes (Williams, *et al.*, 1934; Parrish, *et al.*, 1956), I chose to determine if the staphylococcus type seen in the preliminary study was *Staphylococcus aureus*. Thirty-four captive snakes representing ten species were thus sampled. The species and number of each sampled are as follows: eastern garter snake *(T. s. sirtalis)*, 21; northern ribbon snake (T. sauritus septentrionalis), 3; northern brown snake *(Storeria dekayi dekayi)*, 2; northern water snake *(Nerodia sipedon sipedon)*, 2; eastern king snake *(L. g. getulus)*, 1; eastern hognose snake *(Heterodon platyrhinos)*, 1; sonoran gopher snake *(Pituophis melanoleucus affinis)*, 1; corn snake *(E. guttata guttata)*, 1; boa constrictor *(Boa constrictor)*, 1; indian python *(Python molurus)*, 1. Each was sampled as before. A m-staphylococcus broth tube (for enrichment) and a mannitol salt agar streak plate (for differentiation) were employed for isolation (Benson, 1979). Colonies showing a yellow halo and staphylococcus morphology (five from each positive plate) were subcultured on brain heart infusion agar.

Staphylococci were isolated from ten of the snakes sampled — one indian python, one boa constrictor, one northern water snake, two northern brown snakes, and five eastern garter snakes. The determinations employed and results for these isolates are as follows: morphology — Gram positive staphylococci; growth on mannitol salt agar plate — two mm diameter shiny raised entire colonies show-

ing mannitol fermentation; growth on brain heart infusion agar plate — white to tan colonies after five days at 25° C; growth on blood agar plate — white to tan yellow colonies but no hemolysis even after refrigeration; growth on nutrient agar slant (15% NaC1) — growth within six days; growth in nutrient broth and tryptone phosphate broth tubes — turbid; growth in phenol red mannitol broth tube — slow fermentation in 24 hr.; growth in fluid thioglycollate medium tube — aerobic; DNAase test — varied; coagulase test — negative; catalase test — positive; VP test — negative; novobiocin sensitivity — negative (Bauer, *et al.*, 1974; Benson, 1979). Various positive and negative control strains including a coagulase positive *Staphylococcus aureus* culture were utilized in each determination.

Since these strains did not produce coagulase, hemolyze blood cells, grow anerobically in fluid thioglycollate medium, produce golden pigment, or rapidly ferment mannitol in tube culture they appear not to be *Staphylococcus aureus* but rather to represent relatively non pathogenic species of staphylococci or micrococci (Kloos and Schleifer, 1975; Buchanan and Gibbons, 1974). However the presence of a variety of Gram positive and Gram negative bacteria in the oral cavities (Williams, *et al.*, 1934; Parrish, *et al.*, 1956) and alimentary tracts (Mergenhagen, 1956) of snakes suggests the possibility of infection following a bite. Contamination of a bite wound with saliva and/or feces from the snake could cause this infection.

ACKNOWLEDGMENTS

This research was supported by the Behrend College Faculty Research and Scholarly Activities Fund. I would like to thank Dean Thomas Fox for facilitating this support, Nancy, Michael and Patrick McKinstry for their technical assistance, and John Maljovec for making the preliminary isolations.

INTERSEXUALITY IN A LOGGERHEAD SEA TURTLE, *CARETTA CARETTA*.

The term intersex refers to any specimen which exhibits both male and female characteristics (Miller and Limpus, in press). Forbes (1965) reviewed the widely variable degree of intersexuality that can occur in turtles. Pieau (1975) identified varying degrees of intersexuality at the histological level in embryos of *Emys orbicularis* and *Testuda graeca* even when incubated at constant temperature. However, Bull (1980) expressed the opinion that intersex phenotypes are rare among turtle hatchlings in laboratory and field studies except in a few temperature-shift experiments and he also concluded that intersex phenotypes are rare in natural populations of turtles. Histological examination of gonads of hatchlings *Caretta caretta* and *Chelonia mydas* from natural and laboratory incubation studies by the authors have shown that animals with intersex gonads occur at birth. Because the occurrence of interest specimens is relevant to studies of temperature dependent sex determination, we present the following observations.

C. Caretta, Tag no. X2621, was captured three times in three years in the Lagoon of Wistari Reef about 2 km west from Heron Island (23°27'S, 151°57'E) southern Great Barrier Reef, Queensland Australia. When first captured, 12 May 1976, X2621 had a curved carapace length of 88 cm. It was tentatively classed as a sub-adult male because its tail, although longer than that of a nesting

STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES (Second Edition)

By Joseph T. Collins, Roger Conant, James E. Huheey, James L. Knight, Eric M. Rundquist and Hobart M. Smith

Available in summer 1982. The first edition of this reference, issued in 1978 as SSAR **Herpetological Circular** No. 7, quickly became a standard reference for herpetologists, biologists, zoos, museums, conservation organizations, wildlife societies, book publishers, and Federal and state wildlife agencies. This second, revised edition is an up-date listing over 1300 common and scientific names for species and subspecies of North American (north of Mexico) salamanders, frogs and toads, crocodilians, turtles, lizards, and snakes. New features in this edition (not in the 1978 version) are an appendix of Hawaiian amphibians and reptiles, the inclusion of the names of describers for all genera, species and subspecies, and the addition of a table comparing the number of currently recognized subspecies with those listed in earlier publications. The SSAR Committee on Common and Scientific Names (shown above) considered over 50 proposed changes for this edition, the majority of which were adopted.

***Herpetological Circulars are no longer distributed free to SSAR members; individuals desiring copies of this and future numbers should place their orders as per the above instructions.**

female, was much shorter than those of adult males, which have tails that extend more than 20 cm beyond the carapace. On 9 June 1979, X2621 was recaptured and again classed as a sub-adult male because of its intermediate tail length. The animal was recaptured 29 May 1979; it had increased 1.5 cm in curved carapace length, weighed 80 kg and its tail extended 11 cm beyond the carapace. The front flipper claws were not strongly recurved. Upon being dissected, each gonad resembled a normal testis in colour and size; the epididymus was distinct. Beside each testis was what appeared to be a well formed although narrow paramesonephric duct supported by a mesentry. However, each duct degenerated posteriorly and did not enter the cloaca as a normally developed oviduct would.

Histological examination of the right testis showed advanced spermatogensis within typically structured seminiferous tubules. The investing tunica albuginea showed no abnormal development; the epithelium was squamous. Examination of the structure of the duct revealed a large lumen lined by a squamosal epithelium supported by a thick matrix of muscle and connective tissue. The general structure resembled that of oviducts from mature *C. caretta* except that in normal oviducts the epithelium is columnar.

Two other male *Caretta* from this feeding ground have been dissected. An adult male (curved carapace length = 91.5 cm) displayed the normal external secondary sexual characters of large recurved front flipper claws and very large tail. The second was an immature male (curved carapace length = 80.5 cm) with non recurved claws and a tail not extending beyond the carapace. Both of these latter males lacked paramesonephric ducts.

Although the carapace growth rate (0.5 cm/yr) for X2621 is within the range of sexually differentiating male *Caretta* in the study area (Limpus, unpublished data), the relative slowness in the differentiation of the tail of this maturing turtle contrasts with the more rapid tail development of other presumed maturing male *Caretta* of similar size under observation in the same area (Table 1). There is a distinct possibility that the retention of the well developed paramesonephric ducts was related to the reduced development of the secondary sexual characters of X2621.

Table 1. Growth data from three maturing male *Caretta caretta* inhabiting feeding grounds on reefs adjacent to Heron Island in the southern Great Barrier Reef. (Asterisk (*) denotes captures at which the turtle was classed as a possible female, based on tail length.)

Tag No.	Date	Curved carapace length (cm)	Curved carapace average growth rate (cm/yr)	Tail length beyond carapace (cm)	Tail length average growth rate (cm/yr)
10376	14.07.74*	85.0		2.5	
	31.10.74*	85.0		3.5	
	15.11.76*	86.0	0.8	5.0	1.8
	11.11.78	88.0		8.0	
	02.02.80	89.5		12.5	
X573	02.10.74*	89.0		-ve	
	21.05.77*	89.5	0.5	3.5	1.6
	16.05.80	91.5		9.0	
X2045	04.02.78	89.5	0.7	4.5	4.7
	26.05.80	91.0		15.0	

There are additional "subadult male" *Caretta* in the study area with carapace size and tail length similar to that of X2621 which have shown no major change in tail length over several years. It is possible that there are abnormalities in their gonads and associated ducts.

With sea turtles, insemination is dependent on the male mounting the carapace of the female and having a tail long enough to facilitate intromission. We do not know at present whether or not a turtle such as X2621 would eventually develop a normal adult tail or whether it would be capable of reproducing if its tail did not differentiate further.

There is a need for accurate assessment of the frequency of intersexuality within sea turtle populations and not just within successfully breeding animals. Also there is a need to determine what effect intersexuality has on the reproductive potential of the individual turtle.

IMMOBILITY IN *SOOGLOSSUS GARDINERI* (ANURA: SOOGLOSSIDAE)

While there are numerous anecdotal references to immobility in frogs, there are little quantitative data available and few adequate descriptions of behavior prior to immobility or postures associated with it. I have previously provided references on immobility (Dodd, 1976) and reviewed the importance of immobility as an anti-predator mechanism, especially to small frogs (Dodd, 1977). No published literature records anti-predator mechanisms of sooglossids, a group considered transitional between "Archaic" and "Advanced" frogs, thus of evolutionary importance (Nussbaum, 1980; Lynch, 1973). Current studies on the sooglossids involve various aspects of their evolution, morphology, genetics, and ecological requirements; no observations of potential anti-predator mechanisms have been recorded (R. Nussbaum, pers. commun.).

Observations of immobility in *Sooglossus gardineri* were recorded May 10, 1980, between 0930 and 1220 h, on the southwest facing slope (elevation approximately 600 m) of Morne Seychellois, Island of Mahé, Seychelles. Air temperature was 24.4 degrees C and substrate temperature 26.6 degrees C; the weather was overcast with the sun occasionally breaking through the clouds. A heavy downpour terminated the observations. The frogs were discovered by turning small rocks and other debris next to a small stream. All times were recorded with a stopwatch to the nearest .5 s and an arbitrary maximum limit of 180 s was imposed. Postures and behavior of frogs were noted.

The behavior of six adult *S. gardineri* (9-13 mm, $\bar{x}$ = 11.1) were recorded; a seventh frog, obtained from the core of a fern frond, fell into a deep ravine and was lost for several minutes before found. Five of these frogs showed immobility (1 frog = 82 s; 4 frogs = 180 s) while the sixth began hopping immediately and continued to move approximately 1 m before capture. Two of the frogs hopped once before remaining motionless; one hopped twice. If a frog remained motionless 180 s, the frog was touched lightly or the substrate next to it was distrubed, as by running a stick next to the animal. In none of the four cases did the frog then move. No postures such as crouching (Dodd, 1977) or limb folding (Dodd and Cupp, 1978) were noted. The frogs remained exactly as uncovered.

The habitat where *S. gardineri* is found, forest floor under and between debris and rocks, is deeply shaded even on sunny days. This species is brown dorsally and black laterally, ventrally, and on the limbs. As a result, an individual is extremely difficult to see when uncovered (Fig. 1). The animal shaken from the fern frond was found motionless in the ravine only after several minutes of close search on hands and knees. By remaining motionless, the cryptic coloration would probably have allowed it to escape detection

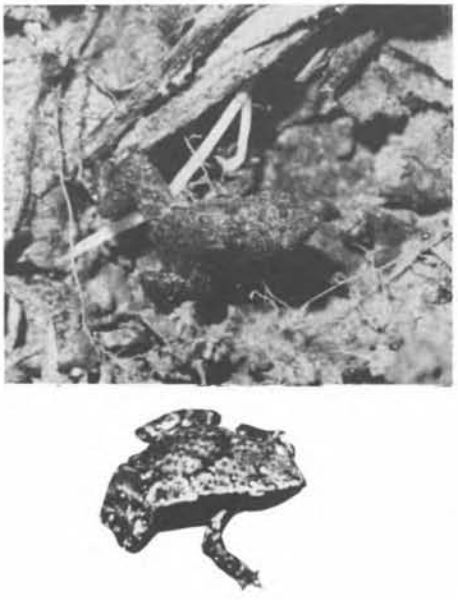

Fig. 1. Immobile *Sooglossus gardineri*. Cryptic coloration coupled with immobility makes the frog difficult to detect in natural habitat.

by a natural predator relying on sight or hearing for detecting prey.

Of importance to understanding the effectiveness of immobility as an anti-predator mechanism to this frog is knowledge about its predators. Unfortunately, there is only an unconfirmed record of caecilians as predators; R. Nussbaum (pers. commun.) believes this record invalid. He also has never found this frog in the stomachs of the sympatric small colubrid *Lycognathophis seychellensis*. It is probable, however, that skinks *(Mabuya seychellensis)* or birds might be predators. This needs to be investigated further.

Immobility coupled with cryptic coloration provides an important means of predator avoidance. A detailed quantitative study of predator avoidance in this species, and for that matter most species of frogs, is long overdue.

ACKNOWLEDGMENTS

I thank Ron Nussbaum for providing information on potential predators based on his extensive research on Seychelles frogs. I also thank Lindsay Andre Chong-Seng, Conservation Officer, Seychelles, for accompanying me in the field.

PUBLIC PERCEPTIONS OF VENOMOUS SNAKES: RESULTS OF AN INTERPRETIVE SLIDE PROGRAM IN MISSOURI

Many wildlife species evoke emotional responses from the public, but few seem to trigger such predictably fearful and negative reactions as venomous or "poisonous" snakes. Though it may be too much to ever expect most members of the public to "like" venomous snakes, educational programs on snakes might help balance the public's view of these animals and promote herpetology-oriented conservation.

A slide program entitled, "Missouri's Venomous Snakes" has been produced by the Missouri Department of Conservation (Johnson, 1980). This 15-minute program features high quality 35 mm photographs and recorded narrative pertaining to Missouri's five species of venomous snakes, and is designed to educate and entertain viewers. Initial showings were at the 1980 Missouri State Fair; ironic, perhaps, in that some displays of reptiles at carnivals and sideshows have done little more than generate snake-related fiction and fear. Viewers of these first showings were asked to participate in a post-program survey to determine their enjoyment of the presentation, as well as their perceptions of venomous snakes before and after the showing. Reiterating, participants gave their pre-program and post-program views of venomous snakes at one time — the conclusion of the presentation. The questionnaire was a self-administered form, seven items in length, and designed to allow even young viewers to respond (Figure 1). Questionnaires were completed by 723 viewers. This group is not purported to represent the "general" public. The following percentages are adjusted for missing values.

Sexes were evenly represented in the group, with males (367) slightly outnumbering females (341). Age was well distributed, also: 21% (143) were 15 years old or younger, 30% (208) were 16-30, 36% (249) were 31-50, and 13% (88) were 51 or older.

Fully 73% (515) of the respondents indicated they had seen or thought they had seen venomous snakes in the wild. One wonders how many of these sightings actually were of venomous snakes, and how many ended with snakes being killed.

When asked to indicate if their pre-program views of venomous snakes were "negative," "neutral," or "positive," 51% (361) said "negative." One-third (235) held neutral views, and 15% (108) had positive views before the show. Negative views were held by 65% (211) of the females compared to only 39% (134) of the males. Youngsters were least likely of all age groups to have negative views: 35% (50) of the respondents 15 or younger checked "negative," compared to 53% (111) of those 16-30, 61% (153) of those 31-50, and 42% (37) of those 51 or older.

Nearly all viewers enjoyed the slide show, with only 2% (11) saying "not enjoyable." Indeed, 64% (455) called the presentation "very enjoyable." Interesting, too, is that 77% (544) said the show was as enjoyable as most other things they had done at the fair — a compliment to the program in view of the wide range of activities available at the Missouri State Fair.

When asked to recall 2 selected points of fact from the presentation, 80% (573) remembered how many kinds (5) of venomous snakes are in Missouri, and 71% (514) recalled that "copperhead" *(Agkistrodon contortrix phaeogaster)* is the most common species in the state.

The slide program apparently had a positive effect on respondents' perceptions, or at least momentary moods, in that only 32% (219) classified their views of venomous snakes as "negative" compared to 51% prior to the show. In fact, 38% (133) of the 347 viewers who felt negatively prior to the presentation changed their views following the program to "neutral" (101) or "positive" (32). The percentage of females changing views from "negative" (37%) about equalled the percentage of males switching views (39%). Overall, 24% (85) of the males viewed venomous snakes negatively after the program, as did 41% (133) of the females, representing decreases in "negative" responses of about 15 percentage points in both groups. Across age groups, decreases in the percentages responding "negative" were substantial. Only 18% (25) of those 15 or younger held a negative view of venomous snakes following the program, as did 31% (64) of those 16-30, 40% (96) of those 31-50, and 32% (27) of those 51 or older.

Missouri Department of Conservation

MISSOURI'S VENOMOUS SNAKES

1. Did you find this show: ( ) very enjoyable ( ) somewhat enjoyable ( ) not enjoyable

2. Compared to most other things you've done at the fair, was seeing this show: ( ) more enjoyable ( ) as enjoyable ( ) less enjoyable

3. How many kinds of venomous snakes are in Missouri? ____ OR ( ) DON'T REMEMBER

4. Which is the most common? ( ) cottonmouth ( ) copperhead ( ) rattlesnake ( ) DON'T REMEMBER

5. Please show (✓) your view of venomous snakes,

	Negative	Neutral	Positive
a. BEFORE the show	( )	( )	( )
AND			
b. AFTER the show	( )	( )	( )

6. Have you ever seen, or think you've seen a venomous snake in the wild? ( ) YES ( ) NO

7. Age ____ And you are ( ) Female ( ) Male

It is safe to conclude that viewers enjoyed the slide program, and that the presentation had a positive effect on some viewers' perceptions of venomous snakes. More and more, biologists and natural resource managers are recognizing that wildlife conservation stems from effective communication with people as much as application of biological techniques. An interpretive presentation like "Missouri's Venomous Snakes" which entertains viewers while fostering understanding and tolerance of the subject thus represents a useful tool in wildlife conservation.

The slide program, "Missouri's Venomous Snakes" (80 slides and cassette tape), can be purchased from the Missouri Department of Conservation. Contact: Film Library, Missouri Department of Conservation, Box 180, Jefferson City, MO 65102.

MEETINGS

APPLICATION OF GENETICS TO THE MANAGEMENT OF WILD PLANT AND ANIMAL POPULATIONS

An international symposium and workshop to be held 9-13 August 1982 at the Washington, D.C. Hyatt Regency Hotel.
Co-chairpersons (*=contact for more information):

* Christine Schonewald-Cox
Natural Sciences Division
National Park Service - 494
Department of the Interior
Washington, D.C. 20240

Steven M. Chambers
Office of Endangered Species
U.S. Fish and Wildlife Service
Department of the Interior
Washington, D.C. 20240

The purpose of this symposium and workshop is to transfer new knowledge and technology to the field of biological resources management with the intent of improving the long-term success and fiscal efficiency of biological resources management programs. Its intent is to short-cut the decades normally required for such information to filter from academic circles to the remote field locations where biological resources management actually takes place.

This symposium and workshop will provide perspectives on the potential contribution of genetics to the management of biological resources. It will specifically address problems associated with the management of wild animal and plant populations, primarily in the temperate zone, as protected areas progressively become more isolated. The isolation of these protected areas, due to changes in peripheral land use and human activities that interfere with historical patterns of movement and migrations between populations, will also be addressed. Other topics to be discussed will include species declines, extinctions, the founding of new populations, the merging of separated populations, and the maintenance of the natural diversity of populations and taxonomic units. The symposium and workshops will identify gaps in our knowledge, and will develop recommendations for interim management practices that could be implemented immediately, as well as for future study to mitigate adverse conditions and trends known to be occurring or anticipated in protected areas. Finally, the symposium will explore possibilities for multidisciplinary, multiinstitutional and multinational approaches to solving the problem of biological resources management in a world vastly different from the one in which many of the protected species evolved.

The symposium and workshop will last 5 days and will consist of an intense schedule of morning talks and of afternoon workshops lasting from 8:00 AM to 6:00 PM. Each day will be devoted to one topic. The workshops will discuss and summarize the limitations and advantages of diagnostic methods for recognizing problems and subjects for additional research, including the testing of the hypotheses in the field.

Daily topics are:

1) The isolation of populations;
2) The extinction of populations;
3) The founding of new populations;
4) The merging of naturally disconnected populations;
5) Preserving the natural diversity of populations and taxonomic units. ●

TAMAULIPAN BIOTIC PROVINCE

Announcing an International Symposium on the Tamaulipan Biotic Province. The Symposium will include all ecological aspects of the biome: vegetation, invertebrates, vertebrates, ecological structure and function, biological resources (use and effects), and management. It will include aspects of applied science and conservation. The meeting will be held at La Quinta Royale Motor Inn, Corpus Christi, Texas, on October 28, 29, 30, 1982. Those interested in contributing papers should submit an abstract by 1 August 1982; abstracts for invited papers must be received by 1 September 1982. For information on either, contact Gene W. Blacklock, Curator, Welder Wildlife Foundation, P.O. Drawer 1400, Sinton, Texas, 78387 or David Riskind, Head, Resource Management Section, Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas, 78744. For information on registration contact Jimmie R. Picquet, Director, John E. Conner Museum, Texas A&I University, P.O. Box 2172, Kingsville, Texas, 78363. ●

CONSERVATION/ LEGISLATION

NEW YORK REVISES STATE LIST OF ENDANGERED AND THREATENED SPECIES

New York State's Endangered Species Unit has recently revised its state list of endangered species. Two new categories are also identified — *threatened* species, which are legally protected, and *special concern* species, which are unofficially listed. During list revision, candidate species were rated according to 23 biological/ecological parameters. These ratings were then used in conjunction with various expert opinions to put species into one of three categories, if appropriate.

The species of reptiles and amphibians which are currently listed by New York are:

Endangered (six species):	
tiger salamander	*Ambystoma tigrinum*
bog turtle	*Clemmys muhlenbergi*
leatherback sea turtle	*Dermochelys coriacea*
hawksbill sea turtle	*Eretmochelys imbricata*
Atlantic ridley sea turtle	*Lepidochelys kempii*
massasauga	*Sistrurus catenatus*
Threatened (six species):	
cricket frog	*Acris crepitans*
mud turtle	*Kinosternon subrubrum*
Blanding's turtle	*Emydoidea blandingi*
loggerhead sea turtle	*Caretta caretta*
green sea turtle	*Chelonia mydas*
timber rattlesnake	*Crotalus horridus*
Special Concern (ten species):	
southern leopard frog	*Rana sphenocephala*
hellbender	*Cryptobranchus alleganiensis*
Jefferson salamander	*Ambystoma jeffersonianum*
blue-spotted salamander	*Ambystoma laterale*
spotted salamander	*Ambystoma maculatum*
spotted turtle	*Clemmys guttata*
wood turtle	*Clemmys insculpta*
diamondback terrapin	*Malaclemys terrapin*
worm snake	*Carphophis amoenus*
eastern hognose snake	*Heterodon platyrhinos*

Anyone planning or contemplating work with any listed species should contact the Endangered Species Unit at the address listed below. A permit and prior approval is required for work with any endangered or threatened species.

The Unit is also soliciting information on the status, distribution, threats to or natural history of any of the species listed. Any information gained will aid in the protection and management of our state's herpetofauna.

The Endangered Species Unit would also like to officially thank those SSAR members who provided assistance and comments during species ratings and list formation. Input from professional herpetologists has allowed the formulation of a list most representative of the status of New York's reptiles and amphibians.

For further information please contact: Patricia Riexinger, Reptile and Amphibian Specialist, Endangered Species Unit, NYS Dept. Environmental Conservation, Wildlife Resources Center, Delmar, NY 12054-9767●

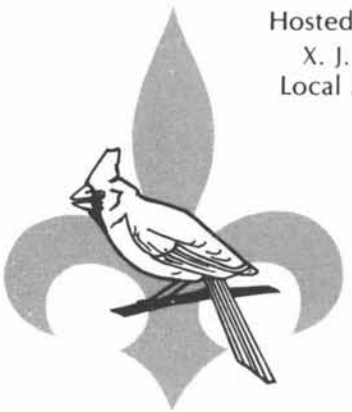
1982 MEETING OF THE AMERICAN SOCIETY OF ZOOLOGISTS

and

AMERICAN MICROSCOPICAL SOCIETY, ANIMAL BEHAVIOR SOCIETY CRUSTACEAN SOCIETY, INTERNATIONAL ASSOCIATION OF ASTACOLOGY, AND SOCIETY OF SYSTEMATIC ZOOLOGY

THE GALT HOUSE
LOUISVILLE, KENTUCKY

DECEMBER 27-30



Call for Papers: April 1982
Abstract Deadline: August 27, 1982
For Oral and Poster Presentations

Housing Rates: $29.00 Singles and $36.00 Doubles
At the Galt House and Hyatt Regency

TENTATIVE SYMPOSIA:

ALTERNATIVE REPRODUCTIVE TACTICS
THE EVOLUTION OF ENDOCRINE SYSTEMS IN LOWER VERTEBRATES
CELLULAR MECHANISMS OF ION REGULATION IN ARTHROPODS
EVOLUTION OF THE VERTEBRATE LYMPHOCYTE
MOLECULAR ASPECTS OF EARLY DEVELOPMENT
GASTRULATION
FACTORS INFLUENCING CRUSTACEAN GROWTH
BIOMECHANICS
CRAYFISH DISTRIBUTION PATTERNS
PHYLOGENETIC RELATIONSHIPS OF THE LIZARDS
EVOLUTION OF NEURAL SYSTEMS IN THE VERTEBRATES: FUNCTIONAL-ANATOMICAL APPROACHES
PROTOZOA AND ALGAE OF BOGS
BIOCHEMICAL ADAPTATIONS OF PARASITES
THE PLACE OF T. H. MORGAN IN AMERICAN BIOLOGY

Hosted by University of Louisville
X. J. Musacchia, Chairperson
Local Arrangements Committee

MISCONCEPTIONS ABOUT THE ENDANGERED HOUSTON TOAD *(Bufo houstonensis)*

A discussion at the Nov. 1980 meeting of the Houston Toad Recovery Team focused on three widespread misconceptions about *Bufo houstonensis* which have been disseminated in a number of publications and unpublished reports. One misconception concerns the importance of enlarged postorbital cranial crests as a diagnostic character of *B. houstonensis*. A number of specimens from Harris County, Texas and some specimens from Bastrop County, Texas do have thickened postorbitals. However, this can hardly be considered excessive enlargement and many specimens have postorbitals of moderate size. Furthermore, specimens of *Bufo woodhousei* having enlarged postorbitals have also been uncovered from localities in Chambers, Hardin, and Jefferson counties, Texas and Beauregard Parish, Louisiana. Thus, the structure of the postorbital cranial crests is variable and often cannot be used alone to identify *B. houstonensis*.

Another misconception is the assumption that pine trees occur at all localities where *B. houstonensis* has been found. A great abundance of natural loblolly pine *(Pinus taeda)* characterizes the locality in Bastrop County, Texas and pines are found at or near some other localities for *B. houstonensis*. However, the pine stand at Lake Woodrow (Burleson County, Texas) was planted by man in 1959 (Thomas, 1977). Also, the habitats at the Skyscraper Shadows/East Haven locality and Fairbanks locality (both in Harris County, Texas) were prairie without pines before being developed for housing (W. McClure, pers. comm.). A common characteristic of all known localities for *B. houstonensis* is friable sandy soil (Brown, 1971; Kennedy, 1962) which, coincidentally, is conducive to pine growth. It thus seems probable that the toads are reliant upon the substrate but not the presence of pine trees.

The last misconception is the emphasis often placed on the importance of natural hybridization as a cause of the trend toward extinction. There is actually little evidence that natural hybridization has had such an effect. Only 20 confirmed natural hybrids (16 *B. houstonensis* X *B. valliceps*, 4 *B. houstonensis* X *B. woodhousei*) have been located (Brown, 1971). The majority of these hybrids were found at one location (Barking Dog Pond, Bastrop County, Texas), and all of these hybrids were found in only two years (1965,1966). There is no evidence of widespread natural hybridization, backcrossing, or introgression. Brown (1971) only indicated the *potential* of natural hybridization to contribute to the trend toward extinction. The most important causes of the decline of *B. houstonensis* are probably destruction/modification of habitats and climatic changes.

TECHNIQUES

A PHYSIOLOGICAL (RINGER'S) SOLUTION FOR ANOLINE LIZARDS

During the last two decades there has been a tremendous increase in research concerning reptilian physiology. Many of these studies have utilized mammalian or avian physiological solutions modified for cold-blooded animals (e.g. Munsick's solution: Munsick et al., 1960; Tyrode's solution: Hoar and Hickman, 1975). A review of the major sources containing formulae for physiological solutions reveals a lack of preparations designed for use with specific reptilian genera (Humason, 1972; Hoar and Hickman, 1975; McDonald, 1976). One of the reptilian species extensively studied is the lizard *Anolis carolinensis*. To my knowledge, there are no physiological solutions designed for this species based on its reported blood chemistry.

Recently, our laboratory had a need for a physiological solution specific for anoline lizards. This solution was designed using the plasma ion concentrations reported for *A. carolinensis* (Dessauer, 1952, 1970; Hutton and Ortman, 1957). The compounds and their amounts used to make one liter of anoline physiological solution are given in Table 1. The osmotic concentration of this solution, as measured with an osmometer, is 360.9 mOs/liter. The pH of anoline plasma at 32° C is 7.26 (Dessauer, 1970) and is similar to that measured for this solution (pH at 32° C = 7.2).

This anoline Ringer's solution has been used in physiological studies dealing with *in vitro* oviductal contraction (Guillette and Jones, unpublished) and *in vitro* ovulation in *A. carolinensis* (Jones and Guillette, unpublished). Survival of tissues in the above studies (performed at 32° C) using the anoline Ringer's solution was 4 times greater than in Munsick's Solution. Additionally, anoline Ringer's has been used with other reptilian species, notably in studies concerning *in vitro* oviduct contraction in *Sceloporus jarrovi* (Guillette, unpublished), physiology of the parietal eye in *Iguana iguana* (Jenison and Nolte, 1980), and red blood cell morphology and culture in *Cnemidophorus lemniscatus* (Serena, 1980). As observed in these studies, anoline physiological solution is useful in different types of experiments (especially *in vitro* studies) and can be used successfully with lizards other than *A. carolinensis*.

TABLE 1: DATA FOR ANOLINE PHYSIOLOGICAL SOLUTION

Compound	Amount used[a] (grams)	mM/L
$MgSO_4 + 7H_2O$	0.27	1.1
$NaHCO_3$	1.30	15.4
$NaH_2PO_4 + 1H_2O$	0.36	2.6
$CaCl_2$	0.32	2.9
KCl	0.34	4.6
NaCl	8.11	139.0
Glucose	1.72	10.5

[a]The amounts of each compound shown in this column are placed in a 1 liter volumetric flask. Flask is then brought to volume using distilled water.

Information on other regional herpetological societies throughout the world is needed to complete and up-date this list. Please send all regional society address changes, corrections, and additions to: John C. Murphy, 201 Peerless Dr., Plainfield, IL 60544 USA.

Editor's Note: This is John Murphy's final contribution as Regional Societies Section Editor. My thanks to John for his efforts as section editor, and my welcome to Jan Perry to that role. Please send all correspondence to her (see inside front cover). ●

THE KANSAS HERPETOLOGICAL SOCIETY

The Kansas Herpetological Society is a non-profit organization composed of professional and amateur herpetologists and naturalists. Founded in May of 1974, the Society is dedicated to promoting the science of herpetology through education, by encouraging scientific endeavor, and by working for the conservation of wildlife in general and of Kansas reptiles and amphibians in particular. Consisting of approximately 165 members, the Society maintains a strong tradition of field work and community interaction. Field trips to poorly known and biologically interesting areas of the state are normally held twice in the spring and once in the fall. Regular meetings are held periodically throughout the year, usually with at least one meeting being held at the University of Kansas Natural History Museum in Lawrence and one at the Sedgwick County Zoo in Wichita. The annual meeting is held in November at the hometown of the current president. Meetings always include a number of interesting talks of semi-technical or travelogue nature and are free and open to the public. Since its inception in 1974, the Society has been responsible for the addition of 525 new county or maximum size records as well as the addition of an amphibian species to the state herpetofaunal list.

The Society currently issues its *Newletter* quarterly to all members and publishes a variety of articles. The *Newsletter* is edited by Hank Guarisco with assistance from Ray Lorraine. Under the editorship of Guarisco, the *Newsletter* has increased in size to approximately 25 pages and includes news of the Society's activities, natural history notes, notes concerning endangered or threatened forms, articles on husbandry, requests for information, and non-live animal advertisements of interest to herpetologists. In addition, the *Newsletter* periodically reprints articles of interest to concerned citizens from other conservation oriented organizations. The November 1981 *Newsletter* represents issue #46. Persons are encouraged to submit manuscripts, pen and ink drawings, or interesting photographs and should send them directly to the Editor, K.H.S. Newsletter, c/o Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. The Society also exchanges newsletters with other regional conservation organizations and any society wishing to set up a reciprocal agreement should contact the Editor.

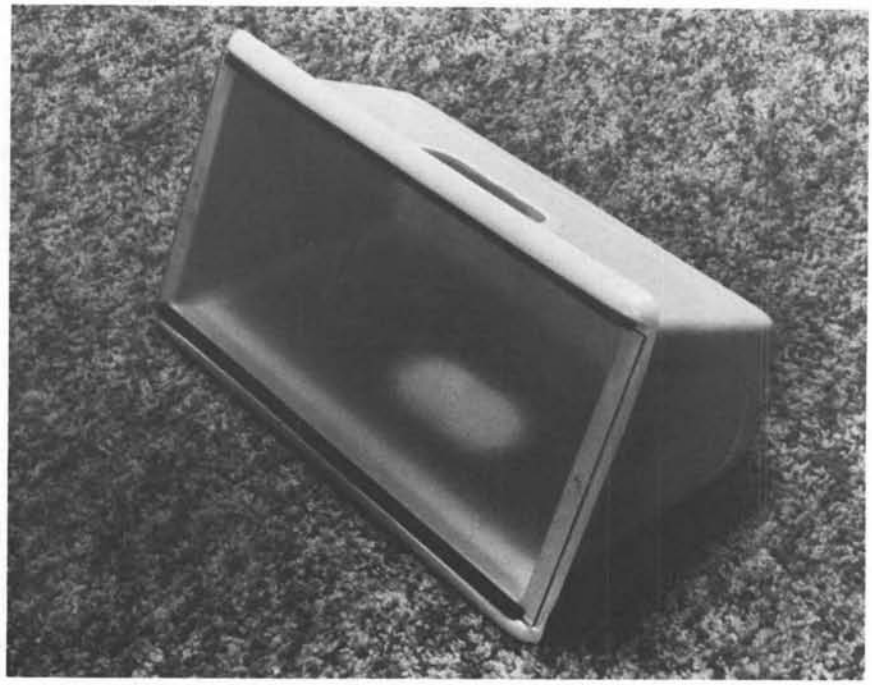
The K.H.S. maintains three standing committees. Two of these (the Membership and Program Committees) are concerned with the internal affairs of the Society while the Legislation/Conservation committee regularly reviews pertinent changes in local or national legislation. The Society also maintains liaison representatives with the Kansas Association of Biology Teachers, the Kansas Academy of Science, the Oklahoma Academy of Science, and the Kansas Chapter of the Wildlife Society. Governance of the Society is by an Executive Board consisting of five officers (elected by the membership) and the Editor. The financial condition of the Society is healthy and is due in large part to the dedicated efforts of the officers and the committee chairpersons. Because of this, the Society has been able to maintain a remarkably economical $4.00 membership fee.

In 1980 the Society applied for and received a $200.00 Regional Society Grant-in-Herpetology from the Society for the Study of Amphibians and Reptiles for the publication and distribution of a brochure concerning the six species of reptiles and amphibians determined by state legislature to be threatened or endangered within the state. Additional monies are forthcoming from local agencies and the K.H.S. anticipates the publication of a textual brochure with six color photographs and distribution maps early in 1982. ●

DUTCH SNAKE SOCIETY (NEDERLANDSE DOELGROEP SLANGEN)

The society, established in 1980, publishes *Litteratura Serpentium* on a bi-monthly basis (6 issues annually), totaling *ca.* 500 pages per volume; photos may be color or b/w, and articles are accompanied by English summaries. Membership is open to anyone interested in snakes. DSS officers are:

President: P. Stoel, Verlengde Hoograven seweg 165, 3525 BE Utrecht.
Secretary: R. Verbeek, Alholm 76, 2133 DD Hoofddorp.
Treasurer: E. den Ouden, Krugerstraat 33, 3531 AN Utrecht.
Editor: A. B. van Woerkom, Baarnseweg 6a, 3735 MG Bosch en Duin.



Membership information is available from the secretary. ●

PYTHONS & BOAS

Authentic 9 x 11 reproductions of antique B&W illustrations of the Boidae, with emphasis on scalation and coloration patterns. Print #4 is now available featuring *Candoia, Eunectes, Eryx jaculus, Trachyboa gularis,* and *Tropidophis* species. The price is $5.95 + $1.50 postage and handling. Reptile Reproductions, P.O. Box 39307, San Antonio, TX 78218-1307.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

REPRODUCTION IN CAPTIVE BLACK PINE SNAKES *PITUOPHIS MELANOLEUCUS LODINGI*

The Black Pine Snake *Pituophis melanoleucus lodingi*, a melanistic subspecies of a widely distributed North American genus, is restricted to the longleaf pine belt of southwestern Alabama, southern Mississippi, and southeastern Louisiana (Conant, 1975). Its limited habitat has been severely damaged due to logging and agricultural activities prevalent in this region (Wright and Wright, 1957). This snake is now listed as an endangered species in the state of Mississippi (Cliburn, 1980). *P. melanoleucus lodingi* has rarely reproduced in captivity and information on reproduction is scarce in the literature. Bowler (1979) mentioned that the subspecies had reproduced successfully at the Philadelphia Zoo. There appears to be no description of newly hatched individuals. The purpose of this paper is to report details of reproduction in captive *P. melanoleucus lodingi* and to describe the hatchlings.

On 29 May 1979, a male *P. melanoleucus lodingi* (1701 mm total length) was received. A female (*A*, 1676 mm total length) was obtained on 21 June 1979. On 19 March 1980, a second female (*B*, 1346 mm total length) was added. All snakes were collected in Mobile County, Alabama, and were jet-black dorsally and ventrally, with light brown caudals and mahogany brown labials. The only distinctive difference in coloration among these snakes was the presence and extent of the white gular patch, which was dissimilar in all individuals.

Specimens were housed individually in 113 liter aquaria in a room illuminated with two 40 watt fluorescent tubes and two 200 watt incandescent bulbs. The photoperiod was similar to that described by Wagner (1979), ranging from 7 h of light in December to 19 h in June and July. Temperature was allowed to fluctuate to match environmental conditions. Summer temperatures usually ranged between 25-32 C. From 1 November through 1 March the daily temperature ranged between 9-18 C. These sharp daily fluctuations did not appear to have any deleterious effects on the snakes. Humidity averaged 60% in summer and 40% during winter months.

Specimens were fed from 15 March through 15 October. They were not offered food during four months when they were artificially hibernated. They were offered initially live and dead laboratory mice and rats, on which they fed sporadically. In June 1980, they were switched to a diet of live chicks and began to feed regularly.

The male and female *A* were first introduced to each other in early March 1980, along with an additional pair from another collection. They were all placed in a large cage with floor dimensions of 1.5 X 2 m. No reproductive activity was noted and the snakes were separated the latter part of May.

On 1 April 1981, the original pair was again introduced. No breeding activity was observed. On 15 April 1981, female *B* was introduced. For several days, during the first few hours of light, the male was observed pursuing female *B* around the cage. Occasionally he crawled over her and bit her neck. He attempted intromission without success. On 21 April 1981 at 0930 h female *B* was observed to have a prolapsed cloaca, and the male was crawling off of her. On the substrate, below the vent of the female was a drop of fluid which, upon microscopic examination, proved to contain spermatozoa. The prolapsed condition of the cloaca of female *B* corrected itself by 0945 h. No further activity was observed and the snakes were separated on 1 May 1981.

Female *B* began refusing food on 7 May 1981, and her girth soon increased noticeably. On 20 May 1981 ecdysis occurred. On 29 May 1981 at 1300 h, oviposition began and was completed by 1700 h. Seven cream white eggs were laid. Six were adherent and no attempt was made to separate them. The single non-adherent egg measured 88 X 40 mm. The other eggs were not measured. All eggs were incubated in an 11 liter plastic box on a medium composed of 255 g of coarse vermiculite and an equal amount (by volume) of water (Tryon, 1975). The box was sealed tightly with the exception of small holes drilled in the sides for air flow. Temperature inside the box was maintained between 24-31 C but was allowed to drop as much at 6 C at night. Incubation took 65-68 days.

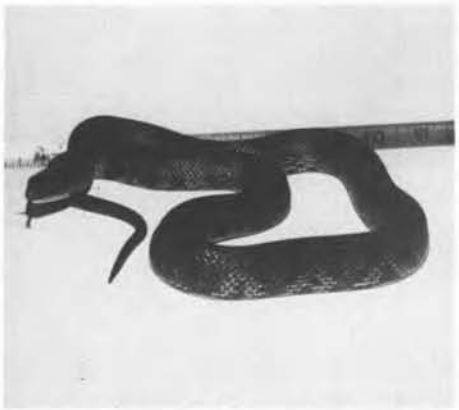

Figure 1. Juvenile *Pituophis melanoleucus lodingi* one month after hatching. Photo by Diane Hall.

The seven hatchlings ranged from 481-533 mm ($\bar{x}$=516 mm) in total length. They differed considerably from the adults in color and pattern. The posterior 75% of the body was distinctly patterned, consisting of black blotches five to seven scales wide. Between these blotches were narrower black blotches one to two scales wide. Most of these blotches extended onto the edge of the ventral scales. This pattern was on a dark brown ground color. Anteriorly, the pattern became more obscure as the ground color darkened. The anterior 25% of the body was completely jet-black, with no trace of pattern. Labials were dark brown to light gray, varying in each individual. The iris was yellow posteriorly and black anteriorly. As with adult *P. melanoleucus lodingi*, the white gular patch was the most variable feature, and was used as a convenient means of identifying each snake. Ventral ground color varied from tan to pink, with differing amounts of black blotching and suffusion.

Ecdysis occurred seven to ten days after hatching. All hatchlings fed readily on live or dead newly weaned mice.

ACKNOWLEDGMENTS

I thank Dr. James S. Jacob for critically reviewing the manuscript, and Dr. Michael Douglass, D.V.M., for providing invaluable assistance. I am especially grateful to my wife Ann, for the encouragement she unfailingly gave.

REPRODUCTION IN CAPTIVE URACOAN RATTLESNAKES, *CROTALUS VEGRANDIS*

The Uracoan rattlesnake, *Crotalus vegrandis*, is confined to savannahs and alluvial plains in the Venezuelan states of Monagas and Anzoategui (Lancini, 1966). There is little published information concerning reproduction in this species. Lancini (1966) found three to four embryos in each of five females captured in December and Murphy, *et al.* (1979) reported dates of birth and weights and lengths of young in four litters of 3-6 young each from wild-bred females. From 1970-1980 six litters were born at the Houston Zoological Gardens (HZG), Texas, all but one the result of captive breeding.

In the summer of 1970, a male and two females were captured in the wild and arrived at the HZG on 9 July 1970. These specimens and subsequent offspring were either exhibited or kept in various sized aquaria. The exhibits (80 X 90 X 140 cm) were glass-fronted and contained a substrate of gravel, large rocks and plastic plants. Light was provided by four 20 watt Vita-lite tubes (Durotest Corp.). Temperature averaged 28° C and the relative humidity was *ca.* 75 percent. The aquaria had paper substrates and hide boxes. Temperature averaged 28° C with a relative humidity of *ca.* 75 percent. Water was available *ad libitum* and adults were fed adult mice every 14-21 days. All specimens were maintained under a 14L:10D photoperiod throughout the year. Specimens were occasionally separated and reintroduced in attempts to induce reproduction. From October through April, a 250 watt sun lamp (Westinghouse Electric Corp.) was placed about one meter above the substrate to provide extra heat and ultraviolet radiation. From May through September, the adults were sprayed with water several times a week to simulate a wet season. Specimens were weighed on a triple-beam balance and lengths were obtained using the squeeze box technique (Quinn and Jones, 1974).

Misting often stimulated the males to begin reproductive behavior, as did introducing a male from one cage into another. Courtship was observed throughout the year (eight of 12 months) but occured most frequently in June and July. Copulation was observed in October 1975 and on 16 September 1980. The 16 September occurrence lasted at least five hours, after which observation was discontinued.

Table 1. Birth dates, number of young, lengths and weights of young *C. vegrandis*.

Date	Number of young	Total length (mm) $\bar{x}$ (range)	Tail length (mm) $\bar{x}$ (range)	Weight (g) $\bar{x}$ (range)
9 July 1970	3	—	—	—
8 June 1976	2	—	—	—
12 May 1978	3	265(250-277)	22(21-24)	13.2(12.0-14.0)
2 May 1979	6	262(230-280)	—	15.1(11.5-16.5)
25 April 1979	8	248(225-265)	—	12.9(11.9-14.4)
30 April 1980	8	265(254-275)	25(20-27)	13.2(11.6-14.3)

The five births that were a consequence of captive breeding occurred during a six week period from 25 April to 8 June. Data from wild-bred females indicate that births in the wild may occur somewhat later. A female captured in the wild during the summer of 1970 gave birth on 9 July 1970 at the HZG. Murphy, *et al.* (1979) reported on four wild-bred females that were collected between 6-8 June and gave birth on 21, 24, 29 June and 9 July.

Birth dates, number of young per litter, weights and lengths of young are given in Table 1. The number of young resulting from captive-bred births varied from 2-8 ($\bar{x}$=5.4). Data on 10 wild-bred females from this study, Lancini (1966) and Murphy, *et al.* (1979) vary from 3-6 ($\bar{x}$=3.6).

The total length of all young measured in this study was 225-280 mm ($\bar{x}$=259 mm). Murphy, *et al.* (1979) reported a total length of 230-279 mm ($\bar{x}$=254 mm) for three full-term wild-bred litters.

According to Klauber (1972), male *C. vegrandis* have 25-31 ($\bar{x}$=27.0) subcaudal scutes and females have 18-25 ($\bar{x}$=21.0). There

is no published information on sexual dimorphism in tail length for this species. The litter of eight young born 30 April 1980 were measured one day after birth and later probed to determine sex; the subcaudals were counted. Tail length-total length ratios were also determined for two adult males and one adult female. Tail length, expressed as a percentage of total length was 9.9-10.6 ($\bar{x}$=10.2) for newborn males (N=5) and 7.8-8.7 ($\bar{x}$=8.1) for newborn females (N=3). The percentages for two adult males were 11.4 and 13.0. The figures for the adult female was 8.1. Subcaudal counts for males (N=9) were 29-32 ($\bar{x}$=30.2) and 22-26 ($\bar{x}$=24.2) for females (N=5). This increases the range of variation for both sexes by one.

The largest adult reported by Klauber (1972) and Lancini (1966) was 684 mm in total length. A male and female presently living at the HZG measured 854 and 761 mm respectively on 26 May 1980.

All young shed for the first time 2-24 hr after birth.

ACKNOWLEDGMENTS

We thank the staff of the Department of Herpetology, Houston Zoological Gardens for their assistance. Specimens will be placed in the University of Texas at Arlington Collection of Vertebrates upon their deaths.

EFFECTS OF HANDLING ON REPTILE EGG HATCHING

There is little agreement among reptile breeders as to methods of incubating eggs, with nearly everyone having his own unique method. Disagreement can be found in almost any element of egg incubation, from type of substrate to temperature. One area of interest concerns the handling of eggs during incubation. Workers such as Frye (1973), and Tryon (1975) state that reptile eggs should not be handled, or at least not turned, during incubation. On the other hand, Pawley (1962) handled *Natrix natrix* eggs daily and found little effect on hatching success. Kauffeld (1969) rotated an adhered clutch of 11 *Pituophis* eggs and 9 subsequently hatched. Riches (1976) stated that turtle and crocodilian eggs should not be handled, but that handling had little effect on snake eggs. Yet Drajeske (1974) found that turning the eggs of *Chrysemys* and *Terrapene* did not adversely affect hatching. Recent reports by Bustard (1972) and Limpus *et al.* (1979) indicated that handling reduced hatching success in sea turtle eggs. Pooley (1971) stated that the eggs of crocodilians should not be handled.

Except for Limpus *et al.* (1979), controlled experiments and quantified results are largely lacking in the cited work. In this paper, the effect of handling on hatching success in two snakes *(Elaphe guttata* and *Python molurus),* a lizard *(Eublepharis macularius)* and a tortoise *(Geochelone carbonaria)* is experimentally tested and discussed.

MATERIALS AND METHODS

The eggs used in the experiments were from clutches laid by animals in breeding groups at the National Zoo during 1977, '78, '79. Whenever possible, an effort was made to use eggs from a single clutch for both control and experimental groups.

The basic incubator set-up was similar for all eggs. They were incubated in slate-bottomed, 10 gallon aquaria with glass tops. Eggs were placed in the aquaria in two evenly-spaced, parallel rows. Heat was provided by 120 watt heat tapes placed lengthwise under the tanks. Temperature could be regulated by thin wooden staves under the aquaria, thus raising or lowering them from the heat source. Temperatures of all aquaria were taken daily. The aquaria were in a windowless room maintained at an air temperature of approximately 24° C.

Each *Elaphe* egg was placed in a pint jar containing a layer of pea gravel into which water was poured; this was covered with a layer of damp sand within which the egg was half buried. Each jar had a plastic lid with a hole in it. The jars with the eggs were then placed on the bottom of the aquarium. Incubation temperature was maintained at an average of 29° C (21-32° C).

The python eggs were placed on top of potting soil in plastic cups. The containers were put in the incubator on 80 mm deep pea gravel and water was poured into the pea gravel. No water was added to the potting soil, but adequate moisture was available from the atmosphere. The temperature was maintained at an average of 32° C (30-34° C).

The gecko eggs were incubated in a two-to-one mixture of potting soil and sand in a plastic cup. The mixture was initially dampened and additional water was added during incubation if the substrate dried. The cups were placed on a pea gravel/water substrate. Temperature was maintained at an average of 28° C (27-29° C).

The tortoise eggs were incubated in the same way as the gecko eggs but the incubation temperature averaged 27° C (26-28° C).

Eggs and jars for each experiment were individually marked and three groups of eggs established: one unhandled, and two groups that were handled weekly. One handled group was rotated twice along its long axis (end-for-end) and twice along its short axis, leaving the eggs with the same side up each week. The other group was rotated one half turn more on its long axis so that the opposite side was up each week. Handling continued until hatching.

Hatching success in two control groups was inexplicably poor and not representative of normal hatching success for *Python molurus* and *Geochelone carbonaria* at the National Zoological Park (Table 1). Data more typical for unhandled eggs of these species were obtained from clutches incubated in the same way as the experimental groups and these are included in Table 1 for comparative purposes.

In *E. guttata, E. macularius,* and *G. carbonaria* the unhandled (reliable data for *P. molurus* and *G. carbonaria*) and experimental groups did not differ significantly in number of eggs hatched, but in *P. molurus* a significant difference between unhandled and experimentals exists (X^2, $P < 0.05$). The experimental groups were similar in hatching success in *E. macularius* and *E. guttata* but significantly different in *P. molurus* and *G. carbonaria* with those turned right side up having lower success than those turned upside down (X^2, $P < 0.05$).

To determine if handling affected hatchling survival, the animals were followed through one month. Survival was nearly 100% in the handled snakes and lizards, with only one *E. guttata* dying in the first month. In the handled tortoises hatchling survival was much worse with five dying within one month. Three of these were from the turned/inverted group and two from the turned/uninverted group. This 74% survival in hatchlings from handled eggs is significantly different from the 100% survival in the 18 unhandled tortoises (X^2, $P < 0.05$). Animals were examined for abnormalties upon hatching and during their first month. All animals appeared normal except for two tortoises. One hatchling that was in the handled/inverted group had an abnormal saddle-shaped shell, but it has survived to date. Another from an unhandled egg hatched with one eye and has also survived.

It is felt that the results differ in reliability. The high hatching success for all groups in *E. guttata* and *E. macularius* promote confidence in these results. The relatively low hatching success (compared to typical) in *P. molurus* and the overall low success in *G. carbonaria* reduce confidence in these results and more data should be collected for definitive con-

Table I. Hatching success for unhandled and two treatments of handled *Elaphe guttata, Python molurus, Eublepharis macularius* and *Geochelone carbonaria* eggs.

Species and Treatment	No. of Eggs	No. Hatched	% Hatched
Elaphe guttata

Unhandled control	5	1	20
Unhandled*	39	17	44
Turned: same side up	16	6	37
Turned: opposite side up	23	13	56

*Data for typical unhandled eggs incubated in the same way as the control group.

clusions. In any case, some tentative conclusions can be made from this study and some earlier work.

It appears that handling snake eggs, especially colubrids, does not adversely affect hatching success (Pawley, 1962; Kauffeld, 1969). Whether this is true of the boids and other snake families remains to be determined but, at the National Zoological Park, many snake eggs are handled during incubation. Eggs are frequently candled and examined with no apparent effect on hatching success. Lizard eggs are also commonly handled at the NZP with no adverse effect on hatching. The routine handling is carefully done and the eggs are not inverted.

Work with turtle and tortoise eggs indicates that handling may be detrimental. Limpus *et al.* (1979) demonstrated that *Caretta caretta* eggs show a significant decrease in hatching if inverted between 12 hours and 14 days after laying. Bustard (1972) reported a decrease in hatching of more than 23% in green turtle eggs moved to a hatchery. Although there was no significant decrease in hatching in handled tortoise eggs in the present study, the death of five hatchlings from handled eggs before a month indicates that caution should be exercised in the handling of the eggs of chelonians.

Limpus *et al.* (1979) identified a critical period when eggs should not be handled. Pooley (1971) also states that it may be deleterious to move crocodilian eggs late in the incubation period. A critical period may exist for other reptile eggs, but this could not be determined in the present work.

The final position of turned eggs may affect hatchling survival. For two species in the present study, those turned rightside up had significantly lower hatching success than those turned upside down. The limited literature is contradictory on this point, but for sea turtles it is the process of rotating the eggs that is damaging and not the final position (Limpus *et al.*, 1979).

More information is necessary to determine conclusively if handling reptile eggs is detrimental to hatching and hatchling survival. However, it appears that lizard and snake eggs can be handled without a deleterious effect on hatching success.

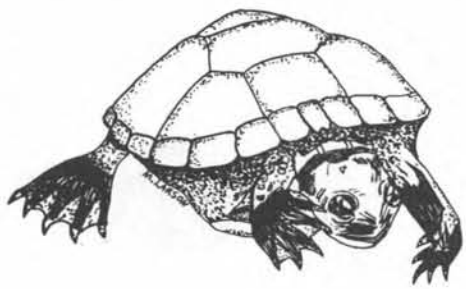
NEWSNOTES



SEA TURTLE IDENTIFICATION POSTER NOW AVAILABLE

The Sea Turtle Rescue Fund of the Center for Environmental Education (CEE), together with the National Marine Fisheries Service (NMFS), have announced the availability of the Sea Turtle Identification Poster, which was jointly developed by the non-profit organization and the federal agency. Seven of the eight species of sea turtles are protected under the Endangered Species Act, which Congress is currently considering for reauthorization. Sea turtle populations have declined around the world due to the destruction of nesting beaches, hunting for commercial trade in their by-products and incidental drowning in fishing nets.

The poster breaks new ground in recognizing the Pacific green turtle *(Chelonia agassizi)* as a separate species. Previously this species had been included as part of the green sea turtle species *(Chelonia mydas).* The poster notes that *Chelonia agassizi* is widely, but not universally, accepted as a separate species.

Printed on a water-resistant surface, the 24 X 36-inch, full-color poster depicts each of the eight species in their natural habitats. Artist Marvin Bennett, under the technical supervision of Dr. Peter C. H. Pritchard, has faithfully rendered each species to allow a sea turtle observer the means of identifying an encountered animal.

Single copies may be obtained free of charge from the NMFS Washington and regional offices or by writing: Charles A. Oravetz, National Marine Fisheries Service, Southeast Region, 9450 Koger Blvd., St. Petersburg, Fla. 33702, telephone (813) 893-3366 or (813) 893-3720. Other materials regarding sea turtles may be obtained by writing: Michael Weber, Sea Turtle Rescue Fund, Center for Environmental Education, 624 9th St., N.W., Washington, D.C. 20001, telephone (202) 737-3600. ●

MALNATE BACK TO ANSP

The Department of Vertebrate Biology welcomes Mr. Edmond V. Malnate, who has retired from The Ullman Organization in Philadelphia in order to devote his time and energy to further studies of the "natricine" snakes, especially those of southeast Asia. A first priority will be completion of his revision (with Garth Underwood) of New Guinean snakes of the genus *Styporhynchus*. He will also continue searches for typical material in the Academy's collections, and will continue to answer queries from colleagues. A newly available herpetological office at the Academy of Natural Sciences will provide a base for these activities. ●

REPTILIAN EMBRYOLOGICAL MATERIAL SOUGHT

Dr. Frank Billett of the University of Southampton and I are in the process of preparing an introduction to the forthcoming volume of the BIOLOGY OF THE REPTILIA dealing with reptilian embryology. It seems appropriate at this time to include a listing of reptilian embryological material available in various institutions. Some such series have been deposited in museums, but many more remain in university collections. We should be most grateful for any advice that can be provided regarding its provenance. When responding, please advise a) the name of the species, b) the age (or size), c) has the material been published on, when, and by whom, d) how many sets, including number of slides are involved. The source of the information will obviously be acknowledged.

AUTHORS SOLICITED FOR SALIENTA ACCOUNTS IN *CAAR*

A number of species in the anuran fauna of the United States have had no authors assigned, or the assignments have been relinquished by their prospective authors. If you would care to volunteer to write the *Catalogue* account for one or more of the species listed below, please contact the undersigned. Accounts available are: *Bufo americanus, B. boreas, B. cognatus, B. debilis, B. exsul, B. microscaphus, B. punctatus; Hyla chrysoscelis, H. cinerea, H. crucifer, H. eximia, H. regilla, H. versicolor; Hypopachus variolosus; Pseudacris clarki, P. nigrita; Rana berlandieri, R. catesbeiana, R. onca, R. pipiens, R. utricularia (sphenocephala); Syrrhophus cystignathoides, S. guttilatus, S. marnocki.* A number of accounts on the generic level are open, too. Richard G. Zweifel, Salientia Editor, Catalogue of American Amphibians and Reptiles, Department of Herpetology, American Museum of Natural History, New York, NY 10024. ●

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1978. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

ANURA

PSEUDACRIS ORNATA (Ornate Chorus Frog). **REPRODUCTION.** *Pseudacris ornata* has been reported to lay egg masses containing 10-100 eggs (Martof, et al., 1980, Amphibians and Reptiles of the Carolinas and Virginia, U. of NC Press, Chapel Hill); an egg mass containing 25 eggs was reported in Alabama (Brown, 1956, The Frogs and Toads of Alabama, Ph.D. diss., U. of AL, Tuscaloosa). No additional information is available regarding number of eggs in egg masses, number of yolked ovarian follicles, or number of oviducal eggs in this common southeastern hylid.

Pseudacris ornata egg masses were collected in a semi-permanent sandhills pond in Marion Co., GA, in the Fall Line Hills physiographic region, on 28 January, 1980. Most egg masses (15 of 23) contained 20-40 eggs; mean egg number per egg mass was 40.50 ($n = 23$; $SE_{\bar{x}} = 9.81$; range = 21-106). Egg masses were attached to submerged grass and sedge stems in shallow water areas open to full sunlight.

Gravid *Pseudacris ornata* were collected in drift fence can traps around the same pond during the period 25 November, 1979-24 February, 1980. Yolked ovarian follicles and oviducal eggs were counted in each female. One frog (SVL = 35.0 mm), collected on 28 January, contained 434 yolked ovarian follicles and 150 oviducal eggs; another (SVL = 34.0 mm), collected on 24 February, contained 487 yolked ovarian follicles and 77 oviducal eggs. Other females in the sample contained yolked ovarian follicles but lacked oviducal eggs. These 20 females ranged in SVL from 30.0-37.0 mm ($\bar{x} = 33.70 \pm 0.76$) and contained 214-848 yolked ovarian follicles ($\bar{x} = 443.05 \pm 77.52$). Number of yolked ovarian follicles in gravid *P. ornata* showed a weak positive correlation with SVL ($r^2 = 0.45$). The female *P. ornata* herein reported were deposited in the Savannah Science Museum herpetological collection.

Submitted by **CHARLES W. SEYLE, JR.**, Research Associate, Savannah Science Museum, 4405 Paulsen Street, Savannah, GA, 31405, and **STANLEY E. TRAUTH,** Dept. of Biology, University of South Florida, Tampa, FL, 33620. ●

RANA PIPIENS (Leopard frog). **PREDATION.** During a recent study of the trophic ecology of largemouth bass, *Micropterus salmoides*, in Lake Rebecca, Hennepin County, Minnesota (Cochran and Adelman, Env. Biol. Fishes, in press), evidence for a seasonal pulse of predation upon leopard frogs was obtained. Young-of-the-year frogs were first observed along the shoreline of the lake on 20 Jul 1978. Since reproductive activity was not noted during the spring, and no tadpoles were ever collected during seining, electrofishing, or fish stomach sampling, it is likely that these frogs had dispersed from a reproductive site elsewhere. This would be consistent with Merrell's (1977, Occas. Pap., Bell Mus. Nat. Hist., No. 15) generalization that young leopard frogs disperse to the shores of large permanent water bodies from breeding sites in temporary ponds without fish. Although they were observed in the immediate vicinity of the shoreline for the rest of the season, frogs were found in only 2 of 404 bass sampled on 8 dates from 17 May-29 Aug 1978. However on 21 Sept, frogs were found in 4 of 84 stomachs, whereas on 5 Oct, 11 frogs were found in 10 of 52 stomachs.

Predation on leopard frogs by bass in early autumn was probably enhanced by increased availability of frogs due to two factors: (1) a die-off of aquatic macrophytes around the edge of the lake, noted in progress as early as 21 Sept, may have in effect removed a "buffer strip" that served to minimize contact between bass and frogs earlier in the season (frogs were found in five bass stomachs that also contained fragments of reeds or other vegetation), and (2) the frogs appeared to spend more time in the water with the onset of cooler weather, as was also noted by Merrell (*ibid.*). A sample of frogs collected on 5 Oct from 1200-1230 were all captured in approximately 15 cm of water with air and water temperatures at 12 C and 14 C respectively. That frogs overwintered in the lake was indicated by the observation of large numbers of dead individuals on the bottom in shallow water after a severe winterkill in March 1979.

The addition of frogs to the diet of bass in early autumn occurred during the midst of a period of high bass growth rates when alternate prey were abundant. Moreover, anglers were observed successfully using leopard frogs as bait as early in the season as late July, supporting the conclusion that low predation rates by bass on frogs at that time were due to low availability of frogs and not to the presence of more highly preferred prey.

Twelve frogs collected on 5 Oct had a mean snout-vent length of 46 mm (range: 40-56 mm), whereas 6 relatively intact frogs found

in stomachs had a mean snout-vent length of 60 mm (range: 48-73 mm). The range in total length of bass that contained frogs was 206-473 mm. One bass that contained a frog on 21 Sept contained 2 frogs when recaptured on 5 Oct.

CAUDATA

PHAEOGNATHUS HUBRICHTI (Red Hills Salamander). **REPRODUCTION.** Within ten years of the discovery and description of *Phaeognathus hubrichti,* the Red Hills Salamander (Highton, 1961, Copeia:65-68), it became clear that it's range was tiny (Schwaner and Mount, 1970, Copeia:571-573) and that the species was in danger of extirpation through habitat destruction (Jordan and Mount, 1975, J. Herpetol. 9:211-215). The species is now listed as "threatened" by the U. S. Fish and Wildlife Service (Federal Register, January 17, 1979, part II, page 3650), the first amphibian in the United States to be so listed (Andres et al., 1976, Ann. Rept., U. S. Fish & Wildl. Serv., 221 p. At least one commercial owner of *P. hubrichti* habitat has agreed to manage it in a manner that will ensure its integrity (Andres et al., 1976).

Despite the need to reserve or manage habitat for this species and to monitor population density, information on demography and reproductive ecology is scarce. Data on oocyte sizes indicate that egg laying may continue to the end of summer, but that most eggs are laid in the spring months (Brandon, 1965, Copeia:67-71; Schwaner and Mount, 1970). Clutches of *P. hubrichti* eggs have not been reported from nature but the size of the largest oocytes (6-7 mm in diameter, Brandon, 1965) and their number suggest the absence of an aquatic larval stage.

In this note are recorded the first instance of egg deposition in this species, in captivity, and a description of the laid eggs.

On 1 July 1976 a female (115 mm snout-vent length), which had been in captivity in the Cincinnati Zoo nearly six years at 7° C (winter) to 18° C (summer) in a 27 X 40 X 9-cm plastic box on damp paper towels, deposited a clutch of 16 eggs. Previous estimates of clutch size based on oocyte complements were 8 and 9 for females 105 and 109 mm in snout-vent length, respectively (Brandon 1965). Until earlier in 1976 the female had been kept essentially in darkness and fed earthworms and crickets weekly. Early in 1976 the room in which salamanders were maintained was equipped with fluorescent lighting regulated to match Cincinnati photoperiod. Thereafter, females of several other species of plethodontid salamanders (*Ensatina eschscholtzii, Plethodon nettingi,* and *P. jordani*) that had been kept for years without reproductive activity also began to deposit eggs.

The eggs of *P. hubrichti* were attached in a cluster, from a common stalk, to the underside of an arched piece of cork bark from which they hung pendulously. The pigmentless eggs were 7-7.2 mm in diameter and were attached to the bark or to other eggs by their outer envelopes. Diameters of eggs plus envelopes were about 8.5 mm. The female was not observed to brood and none of the eggs developed; all were preserved at the first sign of deterioration.

Submitted by **RONALD A. BRANDON** and **EDWARD J. MARUSKA,** Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901; and Cincinnati Zoo, 3400 Vine Street, Cincinnati, Ohio 45220. ●

SAURIA

CNEMIDOPHORUS UNIPARENS (Desert Grassland Whiptail). **BEHAVIOR.** Schall and Pianka (1980, Am. Nat. 115:551-566.) proposed an "escape tactic diversity" hypothesis wherein they described and quantified various escape tactics and the occurrence of tail autotomy in five *Cnemidophorus* species. A species not included in their study was the Desert Grassland Whiptail. I observed a predator-prey interaction between a Sonora Whipsnake, *Masticophis bilineatus,* and a *C. uniparens* in Sawmill Canyon, Pima Co., Arizona, in Upper Sonoran desert grassland. The following is an account of the incident.

On 8/10/81, at 1130 h, I saw the snake actively pursuing the lizard. Both were traveling at a high rate of speed across rocky, open ground for a distance of at least 6 m (I did not see the initial chase), until the lizard attempted to escape into a rock pile of a campfire site. The snake followed the lizard into the rock pile and managed to catch it by the base of the tail. The lizard lost its tail and ran out of the rock pile, stopping in a clearing about 5 m away. When I attempted to photograph the tail-less lizard, it ran back to the rock pile, whereupon the snake immediately captured it, this time across the chest region. The lizard was eventually swallowed.

This field observation documents a naturally occurring incident of tail autotomy in *C. uniparens.*

Submitted by **KATHLEEN GROSCHUPF,** Dept. of Biology, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061. ●

EUMECES FASCIATUS (Five-lined Skink). **MORPHOLOGY.** A bifid tailed *Eumeces fasciatus* (Fig. 1) was captured by George Steward on 23 March 1981 at the base of a rotting stump near Steward's home in Clarksville, Tenn. It was presented to me, alive, on the following day, whereupon it was refrigerated for a few days before being sacrificed, preserved and deposited in the APSU Museum of Zoology (APMZ No. 3312).

The specimen is an adult male measuring 164 mm total length (SV 72 mm, tail 92 mm). The bifurcation is 78 mm posterior to the cloacal opening and appears to have resulted from a dorsal outgrowth of an original, unbranched tail.

Bifid and even trifid tailed individuals of several lizard species have been reported previously (Smith, 1946, Handbook of Lizards, p. 392; Banta, 1963. Turtox News 41:207; Crouch, 1969, Wildlife in Australia 6:101; Goin and Goin, 1971. Introduction to Herpetology, p. 281; and Clark, 1973, HISS News-Journal 1:158). However, this appears to be the first report of such an anomaly in *E. fasciatus.*

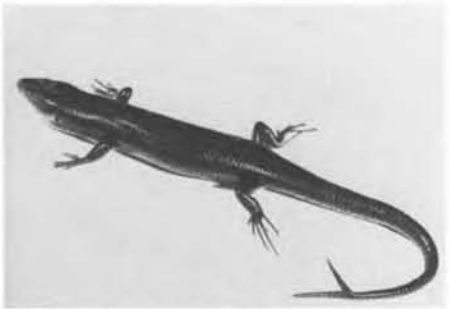

Figure 1. A bifid tailed adult male *Eumeces fasciatus.*

Submitted by **A. FLOYD SCOTT,** Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040. ●

EUMECES FASCIATUS (Five-Lined Skink). **MORTALITY.** An adult female *Eumeces fasciatus* was found dead in a decayed log adjacent to an abandoned beaver pond on the Oconee National Forest, Greene County, Georgia, an apparent victim of an accidental entrapment. The skink was apparently traversing the interior of the decaying log by using the tunnels of some species of wood boring beetle. The skink was stuck in a small hole on the surface of the log, presumably while attempting to exit the tunnel system. The skink managed to squeeze through the small hole as far as the rear legs, which were apparently too wide for the hole. The skink apparently did not try to back up; the rear legs were thoroughly lodged in the hole. The skink probably died as an indirect result of overexposure. When found, the specimen was still limp with no external signs of predation.

SERPENTES

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). **FOOD.** Rat snakes (genus *Elaphe*) are known to feed on a variety of food items (Wright and Wright, 1957. Handbook of Snakes of the U.S. and Canada). However, snakes are rarely reported as being consumed. Yellow rat snakes, *E. obsoleta quadrivittata,* are known to include snakes in their diet (Wright and Wright, ibid.) and cannibalism has been noted in a group of captive-hatched juvenile corn snakes, *E. g. guttata* (Hillis, 1974. Bull. Maryland Herpetol. Soc. 10(1):31-32). An additional incidence of ophiophagy in *E. guttata* is noted here.

In September 1979, the New York Zoologi-

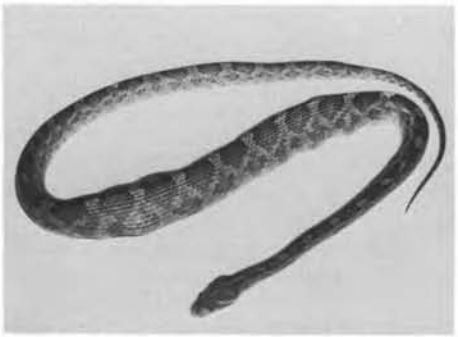

Fig. 1. Adult Great Plains Rat Snake after consuming an adult Texas Garter Snake.

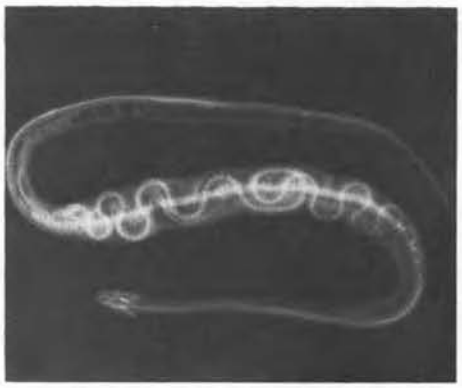

Fig. 2. Radiograph of Great Plains Rat Snake showing the ingested Texas Garter Snake.

cal Park received a shipment of Great Plains rat snakes, *E. guttata emoryi* and Texas garter snakes, *Thamnophis sirtalis annectens*. The snakes were separated into groups of three and four and soaked overnight in plastic barrels (66 cm height, 55 cm diameter). The water depth was 3 cm.

The next morning it was observed (Fig. 1) that a female *E. guttata emoryi* (weight 174 g, snout-vent 85 cm, total length 103 cm) had consumed a female *Thamnophis sirtalis annectens* (weight 94 g, snout-vent 60 cm, total length 77 cm). A radiograph determined that the garter snake had been ingested head first (Fig. 2).

The Department of Animal Health at the New York Zoological Park took the radiograph. Thanks are also extended to Bruce Foster for supplying the photograph.

Submitted by **HUGH K. McCRYSTAL,** Department of Herpetology, New York Zoological Park, Bronx, New York 10460 (present address: Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843.

ELAPHE OBSOLETA (Black Rat Snake). **AUTOPHAGY.** Several cases of ingestion of tails by lizards that have recently autotomized them (autophagy) have been reported; it has been suggested that consumption of an autotomized tail is energetically economical (Vitt, *et al.*, 1978. Ecology 58:326-337, and references therein.). Autophagy is rare in lizards but would be unexpected in snakes since few snakes readily autotomize their tails.

Figure 1. Result of an unusual incident of autophagy in *Elaphe obsoleta*.

On 4 December 1981, a juvenile *Elaphe obsoleta obsoleta* (approx. 300 mm total length) was found by one of us (DE) under a bush at Matoaca Elementary School, Matoaca, Chesterfield Co., Virginia. Discovery of a snake that morning (0845 EST) was unusual since it was raining and cold (4.5°C). The snake was placed in a quart jar for viewing by students. It was cold and, consequently, moved slowly. The jar was placed atop a radiator heater until it was warm to the touch (about 2 min.), then placed on an adjacent windowsill. As it was warming, the snake bit a portion of its tail, about 2cm from the tip. It did not release its grasp but continued to engulf the tail and eventually most of its body. Consumption took about 2 hours and resulted in a circle 4cm in diameter (Fig. 1).

Upon its arrival at the University of Richmond, approximately 5 hours later, the snake was dead. Necropsy revealed that passage of the body continued through the pyloric sphincter and into the small intestine. Consumption behavior resulted in two complete revolutions within the outer circle. The tail was bent about 1.5cm below the anal plate and it circled anteriorly for one-half the circumference of the outer circle. Digestion had not started when the snake died. We suspect death was caused by the snake's inability to inflate its lungs because of pressure from the "meal." The specimen is deposited in the National Museum of Natural History (USNM 225101).

We believe some role in triggering this unusual behavior was played by the sudden exposure of the cold snake to the warm (possibly hot) temperature. One of us (CAP) observed an instance of self-biting (on the tail) by a *Nerodia septemvittata* when immersed in an ice bath. Such sudden and drastic changes in temperature could alter normal neurological and behavioral patterns and result in bizarre behaviors such as described above. Whether snakes exposed to sudden temperature changes in nature exhibit abnormal behavior awaits further observations and/or experimentation. Perhaps a similar unusual behavior observed in the Colonial period led to the hoop snake myth.

ACKNOWLEDGMENTS

Chip Young and Shane Neave helped in the initial phase of this observation.

LEPTODEIRA ANNULATA ASHMEADII (n.c.n.). **ENVENOMATION.** *Leptodeira annulata ashmeadii* is a small rear-fanged colubrid snake that is very common in lowland forests and savannas in Venezuela. It is a snake that is generally regarded as being harmless. I have, during seven years of field work captured and handled numerous specimens of this subspecies without accident.

During 1976, I was attempting to demonstrate the rear fangs of a small (± 30 cm) specimen to two veterinary surgeons, when the snake managed to bite the middle joint of the middle finger of my left hand. Since I did not wish to damage the snake's mouth by pulling it away, nor did I expect to be envenomated, I placed my hand on the floor in order to let the snake free itself. This resulted in the snake chewing on my finger for about 10 seconds. During this time, a very slight pricking sensation was felt at the site. The finger began to swell after 5 minutes, and within one hour was so swollen that it could not be bent. The swelling extended to the wrist within 8 hours. I measured my temperature several times during the first 2 hours and it remained normal. There were no other symptoms apart from a very slight pain to the touch at the site of the bite. I did not seek medical aid because the nearest specialist was 100 miles away. I applied no medication whatsoever, even though I had polyvalent anti-serum (horse anti-*Bothrops, Lachesis, Crotalus*), anti-coral (rabbit anti-*Micrurus*) and a variety of antihistamines available. The swelling went down after three days.

Submitted by **STEFAN GORZULA,** Departamento de Medicina Experimental, I.V.I.C., Apartado 1827, Caracas, Venezuela. Present address: CVG/EDELCA, Departamento de Ecología, Apartado 28, Puerto Ordaz, Estado Bolívar, Venezuela.

MICRURUS FULVIUS TENERE (Texas coral snake). **REPRODUCTION.** An adult pair of *Micrurus fulvius tenere* was donated to the Houston Zoological Gardens (HZG) in late April 1981. Both specimens were collected in Harris County, Texas shortly prior to the donation dates. The pair was placed together for breeding purposes on 12 May 1981. Copulation was recorded shortly after introduction, and the pair was maintained separately thereafter.

A clutch of eight elongate, non-adherent eggs was laid 18 June 1981, 37 days after observed copulation. A small box of damp sphagnum moss was available for nesting purposes but was not utilized. Egg-length ranged from 33-44 mm ($\bar{x}$=36.3mm), egg-diameter from 11-13 mm ($\bar{x}$=11.6 mm), and egg weight from 2.9-4.5 g ($\bar{x}$=3.5 g). Total

clutch weight (28.3 g) was 88 percent of the female's post-ovipositional weight (32.0 g). The eggs were incubated in a vermiculite medium (Tryon, B. W. 1975. Bull. New York Herp. Soc. 11:33-37) and maintained between 25-32° C.

Two eggs slit longitudinally on 5 August 1981. By the morning of 6 August, 49 days after egg deposition, all eight hatchlings had emerged. Sex ratio was five males and three females as determined by total length/tail length ratios. Total length of the eight hatchlings varied from 196-210 mm ($\bar{x}$= 205.2 mm) and weight varied from 2.9-3.3 g ($\bar{x}$=3.1 g). Adults and neonates were released shortly after the hatching date.

A second female was collected between Bryan and Caldwell in Brazos County, Texas shortly prior to its donation to Texas Cooperative Wildlife Collection (TCWC: LA 8101) on 19 April 1981. The specimen was maintained in a 19 liter aquarium with pine bark substrate. Small snakes (*Leptotyphlops, Nerodia* and *Virginia*), lizards (*Anolis*) and hylid frogs were offered as food but all were ignored.

On 10 July 1981, the specimen laid nine eggs. Egg-length ranged from 30-35 mm ($\bar{x}$= 32.1 mm), egg diameter from 14-19 mm ($\bar{x}$= 15.3 mm) and egg-weight from 1.7-3.1 g ($\bar{x}$=2.4 g). Though all appeared dehydrated upon discovery, all were incubated by the above technique at 22-27° C. By 13 July, seven eggs appeared discolored and were determined to be infertile. On 10 September at 0800 h, one neonate had slit the egg and had its head protruding. By 1700 h, the second fertile egg had pipped. Both neonates (TCWC: LA8117-8) had emerged by 0800 h, 11 September after 62 days incubation. Total lengths were 234mm and 238mm ($\bar{x}$=236 mm) and weights were 3.4 g and 3.6 g ($\bar{x}$=3.51 g). The adult female consumed two *Ophiodrys* and one *Nerodia* before being released with the two hatchlings in mid-September 1981.

Reproduction in *M. f. tenere* was summarized by Quinn (1979. Copeia 1979(3):453-463). The HZG account herein is noteworthy as it represents a probable captive-breeding of this form. Though Quinn found sperm in the oviducts of females from October through May, the TCWC female reported herein must have retained viable sperm past May in order to produce fertile eggs in July, 83 days after the date of acquisition. The difference of 12 days in egg incubation time was probably due to the slightly higher temperature range utilized at HZG.

Submitted by **BERN W. TRYON,** Department of Herpetology, Houston Zoological Gardens, P.O. Box 1562, Houston, Texas 77001 and **HUGH K. McCRYSTAL,** Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843. ●

REGINA GRAHAMI (Graham's Crayfish Snake). **COLORATION.** According to the reviews of Hensley (Hensley, M., 1959, Mich. State Univ. Biol. Ser., 1 [4]) and Dyrkacz (Dyrkacz, S., 1981, SSAR Herp. Circ. 11) no instances of albinism in this species has been reported in the literature. On 1 July 1961 I collected a complete albino of this species 1.6 km N of Ganado, Jackson Co., Texas at 6:15 PM AOR. It was an adult ♀, having a S-V length of 524 mm and a tail length of 98 mm. After 20 years of preservation, the eyes are clear with the pupils slightly darkened and the scales slightly yellowed. It is presently in the private collection (EAL 250) of the author.

Submitted by **ERNEST A. LINER,** 310 Malibou Blvd., Houma, Louisiana 70360-2598. ●

THAMNOPHIS PROXIMUS (Western Ribbon Snake). **REPRODUCTION.** A gravid female was collected 2 miles south of Columbia, Boone County, Missouri, on 26 April 1981, by Joe Blum. After being maintained in captivity under natural conditions of light and temperature, the snake gave birth to a litter of five young on 25 June 1981. The female measured 784 mm (TL) and 572 mm (SV) at the time of parturition. The litter is notable for its small size; the previously reported minimum litter size for the species was four (Carpenter. 1958. Herpetologica 14:113-115), but average litter size is twelve (Fitch. 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. No. 52). Also noteworthy is the early date of birth. The previously reported record in the United States was 4 July (cited by Wright and Wright. 1957. Handbook of Snakes of the United States and Canada, Vol. II. Cornell Univ. Press). The sizes of the neonates are also exceptional. Total lengths of the young in this litter at the time of birth were (SV lengths in parentheses): 256 (184), 275 (184), 282 (205), 283 (207), 298 (214) mm. The largest previously reported total length was 280 mm (cited by Behler and King. 1979. The Audubon Society Field Guide to North American Reptiles and Amphibians. Alfred A. Knopf, Inc.). The snake and young are currently being kept and exhibited at Avila College, Kansas City, Missouri. Upon their death they will be deposited in the Bobby Witcher Memorial Collection at Avila College.

Submitted by **ROBERT POWELL,** Avila College, Department of Natural Sciences, 11901 Wornall Road, Kansas City, Missouri 64145. ●

TESTUDINES

EMYDOIDEA BLANDINGI (Blanding's Turtle). **REPRODUCTION.** Graham and Doyle (1979. Journal of Herpetology, 13(1): 125-127.) referred to a clutch of 17 eggs they observed deposited by a captive specimen as the largest reported.

I observed a 22.9 cm *E. blandingi* deposit 19 eggs in captivity between 10 and 18 July 1980. The turtle was obtained from a motorist who had captured it several days earlier on a roadside in Trempeleau County, Wisconsin. The number of eggs deposited ranged from 0-5 eggs per day. $\bar{x}$ egg length: 38.6 mm (range: 38.1-39.0 mm). $\bar{x}$ egg diameter: 19.2 mm (range: 17.7-22.0 mm).

After laying was completed, the specimen was released in the Central Wisconsin Conservation Area. The eggs were incubated at 21-23° C, buried 10 cm deep in slightly moistened sand. After 100 days of incubation, no development was noted and the eggs were opened. All but two of the eggs were infertile. The two embryos were poorly developed.

I wish to thank James Harding and Dr. Max Nickerson for their assistance in obtaining background information for this manuscript.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **BURROW ASSOCIATES.** Landers and Speake (in press, Management needs of sandhill reptiles in southern Georgia, Publ. Proc. Southeastern Assoc. Game and Fish Comm.) summarized vertebrate inquilines occurring in gopher tortoise burrows and included new records for some forms, *e.g. Sistrurus miliarius barbouri.* During an extensive series of tortoise burrow excavations (N = 218) on the Kings Bay Naval Submarine Support Base, Camden County, Georgia, the following snakes were encountered within abandoned gopher tortoise burrows. These snakes were deposited in the herpetological collection at the Savannah Science Museum, to which the specimen numbers refer.

Micrurus fulvius fulvius. Two female snakes were found in tortoise burrows on 19 February 1981. SSM 9564 (720 mm SVL) occurred under leaves in the sunlit entrance of a partially collapsed burrow. SSM 9565 (740 mm SVL) was removed from a small root tunnel leading away from the collapsed lower portion of an excavated burrow; it was about 3 m from the burrow entrance.

Sistrurus miliarius barbouri. We captured two female snakes within the entrances to small tortoise burrows. SSM 9502 (384 mm SVL) was found on 20 February 1981; SSM 9503 (297 mm SVL), on 24 February 1981.

These records are the first documented occurrences of *Micrurus fulvius fulvius* in gopher tortoise burrows and the second reports for *Sistrurus miliarius barbouri* there. It is likely that these snakes were overwintering in the tortoise burrows and, thus, are at least transient members of the gopher tortoise burrow community.

TERRAPENE C. CAROLINA (Eastern Box Turtle). **REPRODUCTION.** Most literature records list seven or eight eggs as the upper limit of a single clutch of eggs from *Terrapene carolina carolina (c.f.,* Ernst and Barbour, 1972, Turtles of the United States); there is one brief note by Zieller (1969. Int. Turtle & Tortoise Soc. J. 3(6):6-9, 30, 31.) of a captive depositing eleven eggs in June 1960.

On 15 June 1980 at approximately 7:00 P.M. a large *T. c. carolina* was located at Wilton, Fairfield County Connecticut in the early stages of nest construction along the tracks of the Penn Central Railroad Company. The first egg was deposited at 9:06 P.M. and a total of eleven eggs were deposited by 9:15 P.M.; nesting was typical for the species. The dimensions and weights of the eggs were

recorded within one-half hour after deposition. The length of the eggs ranged from 24.5 - 37.5 mm ($\bar{x}$ = 33.0, S.D. = 3.525, δ = 12.423), the width of the eggs ranged from 21.5 - 22.5 mm ($\bar{x}$ = 22.3, S.D. = .410, δ = .168) and the weight of the eggs ranged from 8.2 - 10.3 grams ($\bar{x}$ = 9.7, S. D. = .618, δ = .382). A plaster cast was made of the nesting excavation; the throat measures 80 X 70 X 35 mm and the actual egg chamber measures 110 X 90 X 55 mm. Following are the dimensions (straight-line) and the weight of the specimen after nesting.

Carapace (mm)	Plastron (mm)	Height (mm)	Weight (g)
159 X 124	159 X 98	79	746.3

The eggs were moved to an artificial incubator and hatched 18 August 1980; one egg failed to hatch and upon examination of the egg proved to be a near term embryo which apparently died after making the initial break in the egg shell. This specimen is now in the preserved collection of the American Museum of Natural History (AMNH 119636).

The adult *T. c. carolina* was marked and released where found 48 hours after egg deposition and was not recovered during the 1981 nesting season. I suggest the upper limit of eggs for a single clutch from *T. c. carolina* be placed at eleven eggs.

TRIONYX FEROX (Florida Softshell). **SIZE.** This paper presents data on four exceptionally large Florida Softshell turtles that exceed previously published records. All specimens were females. Collection data and measurements are given.

COLLECTION DATA

Turtle 1

Found by Tim Williams and Marvin Brown on State Road 13A north of State Road 207, St. Johns County, Florida, June 30, 1979, 4:30 p.m. (new moon). Donated to St. Augustine Alligator Farm.

Turtle 2

Found by Dennis Magee near St. Johns River, Jacksonville, Florida, Duval County, July 1, 1979. Donated to Jacksonville Zoological Park in care of Ralph Williams, Reptile Supervisor.

Turtle 3

Found by Scott Glasscock on land at the Deseret Ranch, East Hwy 192, near St. Johns River marsh, Osceola County, May 15, 1979. Delivered to Gatorland Zoo, Kissimmee, Florida.

Turtle 4 (see figure below)

Found by John Black near St. Johns River marsh and east of Blue Cypress Lake, Indian River County, crawling on dry land, 4:00 p.m., August 26, 1979. This specimen old, scarred with most of tail missing. Donated to St. Augustine Alligator Farm. I, in turn, delivered to Florida State Museum, Gainesville.

Fig. 1. Photo of RA 4

MEASUREMENTS

Measurements were made with flexible U.S.A. steel tape following curve of carapace, plastron, and then converted to metric. The live turtles were placed on top of eight inch concrete blocks and held by an assistant while measuring. Turtle 4 was measured September 1, 1979, and added to the manuscript. It was measured again September 12th and weight loss of 4 pounds noted and height measurement of ½ inch. This turtle was also measured by square, straight line method, as described by Roger Conant. Turtle 3, the largest, on exhibit at Gatorland Zoo, was measured while in the turtle exhibit pen and weighed by Zoo personnel.

Table 1. Measurements (mm) following shell curve, with straight line measures for RA4 parenthetically.

Number	RA 1	RA 2
Carapace length	603	568
Carapace width	454	456
Plastron length	438	—
Height	114	—
Weight (Kg)	13.72	14.06
Number	**RA 3**	**RA 4**
Carapace length	673	630 (580)
Carapace width	530	482 (410)
Plastron length	469	450 (450)
Height	193	171 (171)
Weight (Kg)	29.48	21.77

Special thanks are expressed to St. Augustine Alligator Farm for Research facilities and travel expenses.

Submitted by **E. ROSS ALLEN,** St. Augustine Alligator Farm, P.O. Drawer E, St. Augustine, FL 32084. ●

NEW DEVELOPMENTS IN HERPETOLOGY AT THE MUSEUM OF COMPARATIVE ZOOLOGY, HARVARD UNIVERSITY

The Department of Herpetology, Museum of Comparative Zoology, is now able, thanks to the National Science Foundation, to offer small sums for travel and per diem to visiting scientists able and willing to revise genera and families in its collections. To advertise this opportunity and because it is our feeling that the MCZ collections have in the past been under-utilized, we here provide a description of the current range and strengths of the collections and of the present plans and research thrust of the Department.

Ever since its founding by Louis Agassiz in 1859, the Department has attempted to be synoptic. Although Agassiz's goal of "typical specimens" from everywhere has never been quite achieved, every curator since Agassiz has endeavored, by international contacts and exchanges, to obtain as broad a coverage of the world's faunas as possible and, *in addition*, has emphasized acquisition of extensive collections from special areas, the latter including large, well-documented series of certain taxa. These efforts over the more than 120-year history of the collections have resulted in an extraordinary research and educational tool that is also an exceptional historical record.

The accessioning policy of the MCZ collection has been, and will continue to be under the new curator, to attempt to concentrate on the two objectives stated above, i.e., 1) to achieve a comprehensive synoptic coverage through an active exchange program and purchase of private collections; and 2) to develop large series of taxonomic groups or of geographical areas.

In regard to the first goal, we are interested in exchanges at the national and international level and lists of our holdings are available for this purpose. We welcome inquiries from other institutions and individuals. In regard to the second goal, each successive curator has had his own areas of special interest and attention: Garman and Barbour, the West Indies; Loveridge, Africa; Williams, the genus *Anolis*, the West Indies and South America. In addition, huge collections from Bougainville and New Guinea were received during Williams' tenure.

The collection now contains about 600,000 specimens in alcohol, more than 2,000 of which are primary types. There are 7,000 skeletons, 20,000 chromosome slides and smaller embryological slide collections. The Herpetology library is enormous, the result of donations by Louis and Alexander Agassiz, Garman, Barbour, Loveridge and E. E. Williams: there are 24 file cabinets of reprints and about 200 shelf feet of books. The coverage of the

herpetological literature is outstanding. Many of the books are old, irreplaceable classics.

The Department is presently undergoing a series of small renovations thanks to combined NSF and MCZ support. The most important is the organization of a skeletal preparation and storage facility. The area, equipped with most wet laboratory facilities (e.g. hood, chemical benches, distilled water, etc.), will allow for the expansion and adequate curation of our already valuable skeletal collection. We hope that these new facilities will further promote the usage of the collection as a research tool.

During his curatorship (he retired from that office in July, 1980), E. E. Williams, while not at all discouraging the collection of amphibians, emphasized reptiles, especially lizards, and in his own and most students' work particularly the genus *Anolis* and its close relatives. (This has resulted in what is unquestionably the best collection of *Anolis* in the world.) Research under Williams' auspices was wide-ranging, from systematics and anatomy to ecology, karyology, and electrophoresis. Biogeography, especially of the West Indies, was a major concern.

Williams continues active work. He and his present and former students continue with their interest in karyotypes and electrophoresis. SEM studies with Jane Peterson have recently flowered. Studies with the latter and Richard Etheridge now extend to the "anoloid" southern South American iguanids that appear to be a sister group or groups to the anolines.

Under the new curator, a change in emphasis is expected. Pere Alberch's group of interest is the amphibians and his research technique comparative and experimental embryology. His incorporation into the MCZ teaching staff has been coupled with the addition, to the Herpetology Department facilities, of a modern laboratory to do histological and embryological work, including live animal facilities. Most of the work in Alberch's laboratory concerns salamanders and it is expected that this will freshen and enlarge the salamander collection, probably the weakest area in the MCZ collection. With the exception of very large collections of *Plethodon cinereus,* made by Williams and students, the salamander collection has remained too snyoptic, with few large series. In spite of its central focus on urodeles, projects involving anurans and snakes are currently being carried out in Alberch's laboratory. Alberch welcomes prospective graduate students interested in any herpetological group as long as the conceptual approach is related to development, evolutionary morphology and systematics.

There are defects we are endeavoring to correct. Until seven years ago there was no geographic file at all. Even now requests for lists of our specimens from specific areas cannot be honored without hardship and expense. Currently, a major effort has been undertaken to complete our geographic file by the end of the 1982 summer. We do maintain species files and routinely xerox our cards on request.

The staff of the Department consists of only one curator and (with the aid of NSF) two curatorial associates. In addition, one or two curatorial assistants are also employed. E. E. Williams continues to assist when he is in residence. The Curatorial Associates are José P. O. Rosado and James L. Knight. Knight, currently interested in the systematics and ecology of some groups of neotropical colubrid snakes, is in charge of the library and of the non-traditional collections. Rosado is the Collections Manager and is in charge of cataloguing, loans, and most aspects related to the maintenance of the main alcoholic collection.

Loan policies are liberal, but visits are encouraged. All requests should be addressed to Dr. Pere Alberch. ●

BOOK REVIEWS

THE NATURAL HISTORY OF MEXICAN RATTLESNAKES. Barry L. Armstrong and James B. Murphy. Special Publication No. 5, Univ. Kansas Museum of Natural History, 88 pp., Dec. 14, 1979. $6.00.

The authors of this book attempt to synthesize the facts of natural history of Mexican Rattlesnakes, based primarily on their own experiences and maintenance of most of the Mexican rattlesnake taxa in captivity. Only three species of their compendium *(C. Stejnegeri, C. catalinensis* and *C. tortugensis)* were not adequately discussed. The first species because it is extremely rare and the latter two because they are island forms and the authors were unable to obtain data on them first hand. I am a little surprised that the authors did not let it be known that they lacked information on the two island forms. There are a number of herpetologists, myself included, who have visited the islands, collected the two species and have substantial field notes on habitat, densities and some on behavior. Nothing was noted for the species, *C. lannomi,* perhaps nothing is known.

The book is remarkably free of errors, I spotted only one typographical error, and the format and layout of the photographs is relatively good. Perhaps only one or two of the 14 habitat photographs could have been improved by the printer. The cover color photographs of the four subspecies of *C. willardi* are exquisite. Photographs of *C. atrox, C. cerastes, C. mitchelli, C. ruber, C. tigris,* and *C. viridis* are not included, the obvious reason being that these are fairly common United States forms and nearly every snake book has photographs of them. However there is no reason why photographs of *C. catalinensis* and *C. tortugensis* were not included, nor those of *C. basiliscus* and *Sistrurus ravus.* I would have preferred to have seen a photograph of the two subspecies of *C. durissus* on a natural background rather than an unpainted piece of plywood.

I was also surprised to see that only the authors collecting localities were recorded as being important for documentation of their field data. I am sure most herpetologists would assume that their stated data were valid without listing the exact localities from where their specimens were taken. In retrospect, it would have been better to have given "up-to-date" distribution maps of the various taxa than to cite the few records to validate their field experience. Their "general description of the region" is so general that nothing is described but citations on where to find descriptions.

Perhaps another point of contention is the detailed "blow by blow" account of breeding behavior in *C. atrox* and *C. pusillus,* while the remainder of the species are somewhat lumped into a standard format summary. If the authors had data on 23 other taxa (so indicated, p. 74), especially the relatively rare island form, *C. catalinensis,* why weren't the data utilized? Only three of 10 lines devoted to the discussion of *C. catalinensis* were utilized to describe its breeding and courtship behavior.

I am relatively sure that there are considerable amounts of natural history data on such common rattlesnakes as *C. atrox, C. cerastes, C. ruber, C. scutulatus, C. mitchelli, C. lepidus,* and *C. viridis* that were not utilized by the authors. Their discussion seems to revolve around only those populations of the above species that occur in Mexico. I have never known a rattlesnake to observe a political boundary, and perhaps in this type of synopsis where one hopes to see a summary of all of the known natural history of a species living in the Sonora or Chihuahua Desert, or the Sierra Madre Occidental, we should not recognize that boundary either. The authors duely cited many authors whose contributions to the study of rattlesnake ecology are extremely important, but failed to utilize much of the data available for a comprehensive account, apparently relying on their own contributions more than their predecessors. Perhaps, as the preface indicates, this was their primary goal. There may have been serious monetary restraints placed on the authors by the editor and publisher of this book and the faults outlined above may have been unavoidable from the authors' view point.

Some positive attributes of the book are the photographs, and the $6.00 price tag. In addition, the knowledge that the authors have concerning rattlesnakes isn't lost to the reader. The data presented are worth having for any student of rattlesnake biology, and I recommend that this book be placed among other herpetological literature as a useful compendium on the natural history of Mexican rattlesnakes.

LES BATRACIENS DE MADAGASCAR. Jean Guibé. 1978. Bonner Zoologische Monographien No. 11:1-144 pp, 1-82 pls. (Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 150-164, 5300 Bonn, West Germany; price 35 DM).

The island of Madagascar has a rich and highly endemic herpetofauna, which has been studied extensively over the past three decades, principally by French herpetologists. Les Batraciens de Madagascar is the culmination of Jean Guibé's investigations on the frogs of the island.

A brief introduction contains an outline of the ecophysiographic regions of Madagascar — two regions and six subregions. The rest of the book is a systematic treatment of the anuran fauna, which consists of three families, 24 genera, and 128 species, plus nine specific names that are unassigned. Keys to the genera and species are included in each familial and generic account. Each genus is diagnosed, and each species account contains a synonymy, diagnosis, and brief statement of geographic distribution. Some accounts contain comments on nomenclature and/or individual or geographic variation. Most of the diagnoses include statements about the osteology of the species.

The book is well illustrated; 364 good pen and ink drawings are grouped on 82 plates. Of these figures, 70 are of frogs, 162 are of hands and feet, and 133 are of osteological characters. The book is printed on high-quality paper (16.5 X 24 cm) and has a good paper binding.

No new taxa are named, but Guibé does make some generic changes. He does not recognize *Boophis* as distinct from *Rhacophorus*, and he elevates the subgenus *Aglyptodactylus* (of *Mantidactylus*) to generic status. He treats *Platyhyla* as a synonym of *Platypelis*.

Eighteen of the 24 genera and all but three of the species are endemic to Madagascar. Of the nonendemic genera, *Rana* is represented by an introduced species *(R. tigrina)*, three genera *(Ptychadena, Tomopterna,* and *Hyperolius)* are shared with Africa, and two genera *(Rhacophorus* and *Microhyla)* are widespread in the Oriental Region.

Guibé's alpha taxonomic treatment of the Madagascaran frogs provides a good foundation for subsequent studies on the evolution and biogeography of the anuran faunas. Such syntheses are needed for an adequate understanding of the evolutionary relationships within the ranoid and microhyloid frogs.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

CAUDATA

AMBYSTOMA CINGULATUM (Flatwoods Salamander). USA: ALABAMA: Houston Co: 4.45 air km S of Gordon; sec. 25, T.2N., R.29E. 26 October 1981. T. R. Jones and J. C. Godwin. Verified by T. R. Jones and J. C. Godwin, Auburn University (AUM 30282-30283). An adult male and female were collected from beneath separate logs in a dry, shallow gum pond basin following moderately heavy rains. The female contained mature ova and deposited an undetermined number of fertile eggs the following day. Larval *A. cingulatum* were collected at this site by T. Lamb and D. Botts on 4 March 1978. These specimens verify the presence of *A. cingulatum* in southeastern Alabama (Mount, R. H. 1975. The Reptiles and Amphibians of Alabama. Alabama Agric. Exper. Sta., Auburn, AL) and as far as we know, the adults are the first adult *A. cingulatum* that have been collected in Alabama since 1910 (USNM 42861, 57389-91). G. Zug kindly supplied the data for the National Museum specimens.

TESTUDINES

CLEMMYS MUHLENBERGI (Bog Turtle) USA: SOUTH CAROLINA: Greenville Co: 2.5 km W Marietta. 23 August 1980. C. E. Putnam, Jr. Verified by D. W. Herman (Atlanta Zoological Park). Clemson University (CU 37-272). One juvenile found basking on a grass clump at 1430 hr; air temperature 25° C. The site is a woodland bog with a canopy of yellow poplar *(Liriodendron tulipifera)* and red maple *(Acer rubrum).* First record for the state and extends the range at least 20 km S from the southern boundary of Transylvania County, North Carolina, where the turtle is known from several localities (Nemuras, K. 1974. Wildl. North Carolina, 38(2):13-15.

Submitted by **DENNIS W. HERMAN,** Department of Herpetology, Atlanta Zoological Park, 800 Cherokee Avenue SE, Atlanta, Georgia 30315 and **CARL E. PUTNAM, JR.,** Rt. 5, Box 37D, Anderson, South Carolina 29621. ●

EMYDOIDEA BLANDINGI (Blanding's Turtle). USA: NEW YORK: Jefferson Co: Millsite Lake, Town of Theresa. 3 July 1981. R. J. Gawlik. American Museum of Natural History (AMNH 120619). Verified by M. W. Klemens. This report extends the species' northern New York range approximately 10 km to the SE of its reported occurrence at Goose Bay Marsh on the St. Lawrence River (Petokas and Alexander, 1978, SSAR Herp. Review 9(3):107) and more clearly defines its range in the St. Lawrence River lowland as described by Petokas and Alexander (1981, New York Fish and Game J. 28(1):119-120). Millsite Lake is deep and cold with steep, rocky shorelines having little aquatic vegetation, and thus does not appear to be suitable Blanding's turtle habitat. We suspect that this individual wandered from its more usual habitat such as the ponds and marshes found in the general area of capture.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ALABAMA: Jefferson Co: railyard in city limits of Birmingham (T17S, R3W, Sec. 27, N½). 7 October 1981. G. Bosworth. Identified by K. R. Marion. University of Alabama at Birmingham Vertebrate Museum (VM-UAB 0368). First record for county and north Alabama. The locality is *ca.* 230 km NW of an isolated breeding colony near a motel in Eufaula, Barbour County (Mount, R. H. 1975. The Reptiles and Amphibians of Alabama, Auburn University Press) and ca. 150 km NW of the only other reported locality in the state, an apparent small breeding population on the Auburn University Campus, Lee County (R. H. Mount, pers. comm.). The specimen was captured under a railroad tie and was evidently introduced by rail from points south. The railyard regularly receives freight shipments from Pensacola, Florida. Several "small lizards" were also seen by workers in the immediate area in the weeks preceding the capture of this specimen, an adult.

Submitted by **KEN R. MARION** and **GREG BOSWORTH,** Biology Department, University of Alabama in Birmingham, University Station, Birmingham, Alabama 35294. ●

SCELOPORUS COUCHI (Couch's Spiny Lizard). MEXICO: NUEVO LEON: Picachos Mts., 9.8 km SW Cerralvo and 10.1 km W on Rancho El Milagro, 11 July 1977, Ernest A. Liner and Allan H. Chaney, EAL 4299 (7 specimens); 9.8 km SW Cerralvo and 10 km W on Rancho El Milagro, Picachos Mts., 15 August 1978, EAL 4560 (4 specimens); 9.8 km SW Cerralvo and 13.3 km W on Rancho El Milagro, Picachos Mts., 15 August 1978, EAL 4564 (1 specimen); 9.8 km SW Cerralvo and 16.7 km W on Rancho El Milagro, Picachos Mts., 16 August 1978, Ernest A. Liner, Richard M. Johnson and Allan H. Chaney, EAL 4569 (4 specimens); verified by Ernest A. Liner. These specimens extend the range eastward approximately 60 km from the nearest known range in the vicinity of Sabinas Hidalgo.

Submitted by **RICHARD M. JOHNSON,** 4170 Lantern Lane, Mobile, Alabama 36609, **ERNEST A. LINER,** 310 Malibou Blvd., Houma, Louisiana 70360 and **ALLAN H. CHANEY,** 1208 W. Richard, Kingsville, Texas 78363. ●

SCELOPORUS POINSETTI POINSETTI (Crevice Spiny Lizard). MEXICO: NUEVO LEON: Picachos Mts., 9.8 km WW Cerralvo and 11.9 km W on Rancho El Milagro, 10 July 1977, EAL 4296 (1 specimen); Picachos Mts., 9.8 km SW Cerralvo and 11.9 km W on Rancho El Milagro, 11 July 1977, EAL 4297 (5 specimens); Picachos Mts., 9.8 km SW Cerralvo and 10.1 km W on Rancho El Milagro, 11 July 1977, Ernest A. Liner and Allan H. Chaney, EAL 4301 (1 specimen); 9.8 km SW Cerralvo and 13.3 km W on Rancho El Milagro, Picachos Mts., 15 August 1978, EAL 4565 (1 specimen); 9.8 km SW Cerralvo and 16.7 km W on Rancho El Milagro, Picachos Mts., 16 August 1978, Ernest A. Liner, Richard M. Johnson and Allan H. Chaney, EAL 4572 (1 specimen); verified by Ernest A. Liner. These records extend the range approximately 60 km east from the previously known range.

Submitted by **ALLAN H. CHANEY,** 1208 W. Richard, Kingsville, Texas 78363, **ERNEST A. LINER,** 310 Malibou Blvd., Houma, Louisiana 70360 and **RICHARD M. JOHNSON,** 4170 Lantern Lane, Mobile, Alabama 36609. ●

SERPENTES

ELAPHE SUBOCULARIS (Trans-Pecos Rat Snake). MEXICO: NUEVO LEON: 35.4 km SW Bustamante, 610 m, 26 July 1979, (fig. 1); 28.3 km W Bustamante, 610 m, 28 July 1981, (fig.

Fig. 1. *Elaphe subocularis.* 35.4 km SW Bustamante, Nuevo Leon, Mexico.

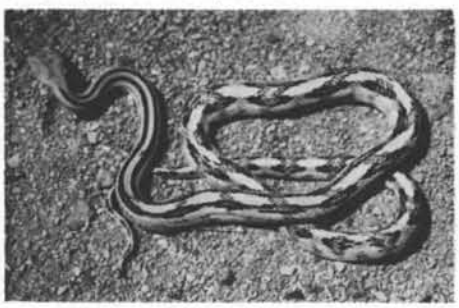

Fig. 2. *Elaphe subocularis.* 28.3 km W Bustamante, Nuevo Leon, Mexico.

2); Ernest A. Liner, Richard M. Johnson and Allan H. Chaney. According to the latest review of this species (Worthington, Richard D., 1980, Cat. American Amph. Rept., 268) these two specimens were collected some distance to the east of the range as depicted and are the most northern localities in Nuevo Leon. They were collected at an archeological site called "Chiqihuitillos" and were photographed and released at the site of capture due to their protected status in the United States. A photograph of each specimen is presented in lieu of a catalogue number for verification.

TANTILLA RUBRA RUBRA (Red Blackhead Snake). MEXICO: NUEVO LEON: 9.8 km SW Cerralvo and 16.7 km W on Rancho El Milagro, Picachos Mts., 457 m, 16 August 1978, Ernest A. Liner, Richard M. Johnson and Allan H. Chaney, EAL 4566 (1 specimen); verified by Ernest A. Liner. This specimen extends the range northeast approximately 90 km from its nearest previously known range of Horsetail Falls and Chipinque, Monterrey in Nuevo Leon.

Submitted by **ERNEST A. LINER,** 310 Malibou Blvd., Houma, Louisiana 70360, **RICHARD M. JOHNSON,** 4170 Lantern Lane, Mobile, Alabama 36609 and **ALLAN H. CHANEY,** 1208 W. Richard, Kingsville, Texas 78363. ●

THAMNOPHIS SAURITUS SEPTENTRIONALIS (Northern Ribbon Snake). USA: INDIANA: Putnam County: Warren Township: East half of the NE quarter of section 16: 1.3 km due south of the Deer Creek bridge on U.S. 40 in Putnamville, Indiana. 11 October 1981. Collected by Jon Hendrix. Verified by James List, Ball State University, Muncie, Indiana, and by Sherman A. Minton, Jr., Indiana University School of Medicine, Indianapolis, Indiana. County record for Putnam County, Indiana, filling a gap near the southeastern limit of the range of the subspecies in the state. Photographs and specimen data are in the herpetology collections of the Department of Biology, Ball State University, (BSU # 821).

Submitted by **J. R. HENDRIX** and **JAMES LIST,** Department of Biology, Ball State University, Muncie, Indiana 47306. ●

AMPHIBIAN AND REPTILE DISTRIBUTION IN COLORADO: CORRECTIONS OF ERRONEOUS RECORDS

SCAPHIOPUS INTERMONTANUS (Great Basin Spadefoot). USA: COLORADO: Moffat Co: Dinosaur Nat. Monument, Castle Park. 25 June 1949. A. H. Fehlman. Identified by G. Hammerson, verified by H. M. Smith. Univ. Colorado Mus., Boulder (UCM 5237, 97 specimens). Erroneously reported as *Bufo w. woodhousei* by Maslin (1959, Univ. Colorado Stud., Ser, Biol. No. 6, p. 14). Metamorphosing and recently metamorphosed specimens differ from *B. woodhousei* of same stages (1) by possessing: a well-developed, hard metatarsal spade; oral papillae encircling the mouth parts; a vertical pupil; and more extensive interdigital webbing; and (2) by lacking: pronounced tibial tuberculation; a well-developed parotid gland; and an outer metatarsal tubercle. First record for county. Extends known range 154 km N. in extreme western Colorado (Smith, Maslin & Brown 1965, Univ. Colorado Stud., Ser. Biol. No. 15, p. 13).

SCAPHIOPUS MULTIPLICATUS (New Mexico Spadefoot). USA: COLORADO: San Miguel Co: Vicin. Gypsum Gap. 9 June 1964. D. Johnson. Identified by G. Hammerson, verified by H. M. Smith. UCM 32286-32287. Erroneously reported as *S. intermontanus* by Secoy and Brown (1968, Southwest. Nat. 13:106). Both specimens have flat frontoparietals and an extensive frontoparietal fontanelle (*cf.* Zweifel 1956, Am. Mus. Novit. No. 1762, pp. 35-37, Fig. 23). Negates major southward range extension for *S. intermontanus* in Colorado. First record for county.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). USA: COLORADO: Bent Co: John Martin Reservoir, N. shore, 9.7 km W dam. 16 May 1959. A. B. Wolfson. Identified by G. Hammerson, verified by H. M. Smith. UCM 32238. Erroneously reported as *P. douglassi brevirostre* by Secoy and Brown (*loc. cit.*). Negates only *P. douglassi* record for county.

SCELOPORUS GRACIOSUS GRACIOSUS (Northern Sagebrush Lizard). USA: COLORADO: Pitkin Co: 1.6 km NE Snowmass, Wheatley Gulch. 17 June 1965. H. G. Rodeck. Identified by G. Hammerson, verified by H. M. Smith. UCM 32689. Erroneously reported as *S. undulatus elongatus* by Secoy and Brown (*loc. cit.*). Negates only *S. undulatus* record for county.

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). USA: COLORADO: Las Animas Co: 37 km E Model, Purgatoire R. 22 June 1963. R. & J. Holland. UCM 31769. 8.0 km W, 40.2 km S Fowler. 14 May 1959. R. Strickland. UCM 31785. Fremont Co: 8.0 km E Florence. 23 August 1964. D. Post. UCM 31784. Otero Co: 35.4 km S Fowler. 15 May 1959. R. Strickland. UCM 31786. Identified by H. M. Smith & T. P. Maslin, verified by G. Hammerson. Erroneously reported as *T. sirtalis parietalis* by Secoy and Brown (*loc. cit.*). Negates reported major range extension out of S. Platte R. drainage.

Submitted by **GEOFFREY A. HAMMERSON,** Department of Environmental, Population & Organismic Biology, University of Colorado, Boulder, Colorado, 80309. ●

HERPETOLOGICAL RECORDS FROM WEST-CENTRAL ARIZONA

In a continuing effort to determine the distribution and ecology of wildlife species in western Arizona, the USDI Bureau of Land Management inventoried reptiles and amphibians on 2.3 million acres of federal, state, and private lands in Yavapai, Maricopa, Yuma, and Mohave counties.

The following herpetological records were determined to be range extensions. Voucher specimens from each separate locality have been placed in the Phoenix District herpetological museum unless otherwise noted. BLM numbers corresponding to records listed in this paper, were assigned to all specimens observed or collected, and can be found in the district's central file records catalog. Vegetative associations listed are based on compilations of Brown, *et al.* (1979).

ANURA

Rana catesbeiana — Arizona: Yuma Co: Centennial Wash, 7 km NW Gladden T7N, R11W, SW, Sec. 26, mesquite-salt cedar woodland in large perennial reservoir, *ca.* 2,010 ft., 18 September 1979 and 29 March 1980 (BLM #4345, 4812-4813). Extends range 95 km N and 100 km E of that illustrated by Stebbins (1966) along the Gila and Colorado Rivers, respectively. This population may be contingent with those along the Gila River during extended wet periods.

Bufo alvarius — Arizona: Yuma Co: Santa Maria River, 9 km NE Alamo Dam, T11N, R12W, NE, Sec. 18, cottonwood-willow riparian, *ca.* 1,280 ft., 13 September 1979, (BLM #4463). Fills in distributional gap between localities reported by Stebbins (1966) along the Colorado River and that of Hahn and May (1972) 42 km to the east. Not collected. Two additional records at Centennial Wash, 7 km NW Gladden, T7N, R11W, SW, Sec. 26, *ca.* 2,010 ft., mesquite-salt cedar woodland, 13 August 1979 (BLM #4333 and 4347).

SAURIA

Eumeces gilberti arizonensis — Arizona: Yuma Co: Harquahala Mountains, 21 km SW Aguila, T5N, R10W, NE, Sec. 6, *ca.* 5,020 ft., open chaparral, 23 August 1979, (BLM #4122). Extends range 50 km W of that reported by Stebbins (1966) near Wickenburg, Arizona. Additional records from Harcuvar Mountains, 23 km NW Aguila, Arizona, T8N, R11W, SE, Sec. 2, *ca.* 5,040 ft., open chaparral, 29 August 1979.

Xantusia vigilis vigilis — Arizona: Maricopa Co: Harquahala Mountains, 21 km SW Aguila, T5N, R10W, NW, Sec. 5, *ca.* 4,880 ft., open chaparral, 30 April 1980, (BLM #5047). Extends range 70 km NE of that reported by Stebbins (1966) in the Kofa Mountains and 105 km S of that reported by Jones, *et al* (1980) in the Wikieup, Arizona vicinity.

SERPENTES

Diadophis punctatus regalis — Arizona: Maricopa County: Harquahala Mountains, 21 km SW Aguila, T5N, R10W, SW, Sec. 31, *ca.* 4,860 ft., open chaparral, 4 October 1979, (BLM #4135) and the Harcuvar Mountains, 23 km NW Aguila, T8N, R11W, SE, Sec. 2, *ca.* 5,050 ft., open chaparral, 11 September 1979 (BLM 4153). Extends distribution 80 km W and 100 km S of that illustrated by Stebbins (1966).

Masticophis taeniatus — Arizona: Yuma Co: Harquahala Mountains, 22 km SW Aguila, T6N, R10W, SW, Sec. 31, *ca.* 5,600 ft., open chaparral, 5 September 1979 (BLM #4131). Additional record from Harquahala Mountains, 21 km SW Aguila, T6N, R10W, NW, Sec. 31, *ca.* 5,480 ft., open chaparral, 27 April 1980 (BLM #4874). One additional record from Harcuvar Mountains, 23 km NW Aguila, T8N, R11W, SE, Sec. 2, *ca.* 5,050 ft., open chaparral, 22 August 1979 (BLM #4147). Extends record 70 km W of that illustrated by Stebbins (1966) near the Prescott National Forest.

Tantilla planiceps atriceps — Arizona: Yuma Co: Harquahala Mountains, 21 km SW Aguila, T6N, R10W, SW, Sec. 31, *ca.* 5,600 ft., open chaparral, 13 and 23 May 1980 (BLM #5235 and 5237, respectively).

Two additional records from Arizona: Yuma Co: Harcuvar Mountains, 23 km NW Aguila, T8N, R11W, SE, Sec. 2, *ca.* 5,050 ft., open chaparral, 8 and 21 May 1980 (BLM #5272 and 5275, respectively). Extends range 55 km SW of Date Creek reported by Hahn and May (1972).

CENTROLENELLA FLEISCHMANNI (BOETTGER): NEW TO THE ANURAN FAUNA OF EL SALVADOR

The frog *Centrolenella fleischmanni* (Boettger) occurs from Guerrero and Veracruz, Mexico south through Central America to Surinam and Ecuador (Duellman, 1977). Starrett and Savage (1973) included El Salvador in the distributional range for this species, although, they did not mention any specimens from that country. On the night of 1 December 1979 Victor Hellebuyck collected an individual of *C. fleischmanni* from under a leaf of a bush along a fast-moving stream at Cantón Monte Negro, 14 km W Matapán, Departamento de Santa Ana, 1686 m. The site of Capture falls within the Subtropical Humid Forest formation of Holdridge (1975). The most common trees at Cantón Monte Negro are *Liquidambar styraciflua, Quercus hondurensis, Q. pendularis,* and *Pinus oocarpa.* This locality is located on the south slopes of the Cordillera de Alotepeque-Metapán in northwestern El Salvador.

The Salvadoran specimen (MHNES 30-859) is a male with a snout-vent of 24.9 mm and agrees in every respect with the descriptions given by Taylor (1952) and Lynch and Duellman (1973). This is the first known record for *C. fleischmanni* and the anuran family Centrolenidae for El Salvador.

I thank René M. Jaime and Victor Hellebuyck of the Museo de Historia Natural de El Salvador (MHNES) for allowing me to examine the live frog and for providing me with access to the museum collections.

AUSTRALASIAN AFFILIATION OF HERPETOLOGICAL SOCIETIES

The Affiliation started on an informal basis in 1974 and was formally established in 1977. Its objectives are to promote the scientific study of amphibians and reptiles and their conservation, to publish the journal *Herpetofauna*, to encourage liaison between the member societies through conventions, publications and field work, and to represent the interests of its member societies at the Regional level.

It is a non-profit co-operative organisation with the prime executive purpose of pooling the publishing resources of member herpetological societies in the Australasian Region. Five societies belong to the Affiliation (one in New Zealand and four in Australia) and another is considering joining. The Affiliation has a complimentary role and function to the Australian Society of Herpetologists in the Region.

PUBLICATIONS

Herpetofauna is published twice yearly and contains original papers and notes on any aspect of Australasian herpetology. Herpetological Notes, Regional News, and occasional book reviews are features of the journal. Member societies bulk subscribe to *Herpetofauna* on behalf of their members. Overseas and Australasian herpetologists who do not belong to one of the affiliated societies are invited to subscribe direct to the Affiliation. An Australasian herpetologists manual (of accumulated loose leaf design) on husbandry, study techniques, breeding, ailments etc. is in preparation.

MEETINGS

Conventions are held for society delegates and visitors about every two years in a field location, or hosted by a member society in its home city. Three productive and successful conventions have been held to date. The last was held in conjunction with the Melbourne Zoo Herpetological Symposium in May 1980. The fourth Convention will be in New Zealand in October, 1981. Societies from adjoining states also hold joint field work meetings.

INVITATION

Overseas and Australasian herpetologists who do not recieve *Herpetofauna* are invited to subscribe (use form below). Back issues are available. Readers of Herpetological Review who subscribe will receive their first copy free with six to follow.

The Editor,
The Australasian Affiliation of
Herpetological Societies,
Box R307 Royal Exchange,
SYDNEY N.S.W. 2000 AUSTRALIA.

Please find enclosed cheque, money order, postal note, etc. to the value of * Aust. $10.00 or $15.00 for six issues of *Herpetofauna* published twice yearly.

Name:

Address:

Zip:

* In Australia, New Zealand or Papua New Guinea $10.00 Aust. (incl. post).

* Elsewhere $15.00 Aust (incl. surface post. $25.00 incl. airmail post).

Please make cheques payable to the A.A.H.S. in Australian currency.
Receipt sent if requested.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the editor.

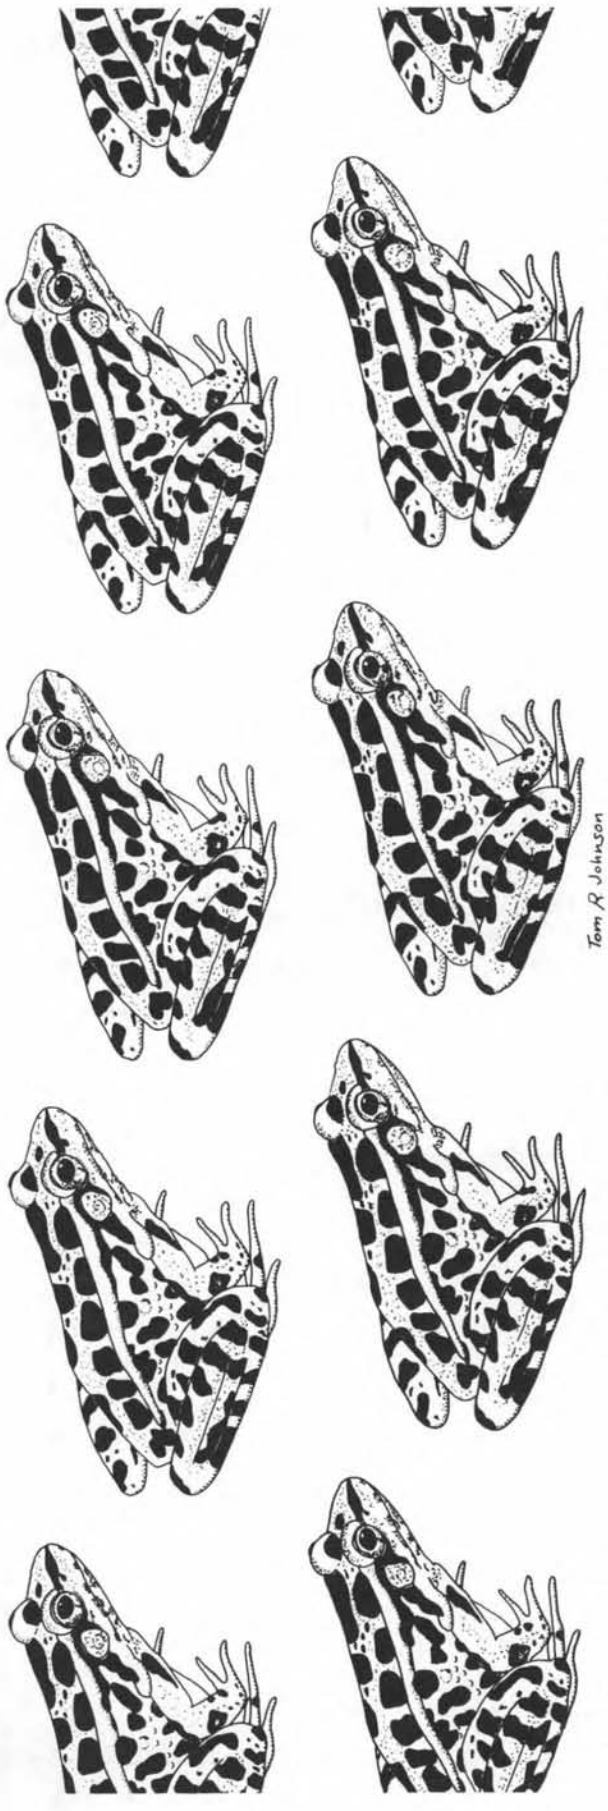
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), **Herpetological Circulars,** and occasional **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1982

(Please send only U.S. funds; make checks payable to SSAR)

Student member	$15.00
Regular member	$18.00
Sustaining member	$30.00
Contributing member	$35.00
Institutional	$30.00



Non-U.S. members should also include $5.00 to help cover rising postage costs.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

MESSAGE FROM THE PRESIDENT 2
SSAR 25th ANNIVERSARY 4
SSAR CONTRIBUTORS 5
LETTER — A BRITTLE BUCKET CAUTION 5
FEATURE ARTICLES
Reproduction and feeding in *Eridiphas slevini* (Serpentes: Colubridae), by L. E. Hunt and J. R. Ottley 8
Parasitic nematodes *(Kalicephalus willeyi)* in a Sri Lankan blind snake, *Typhlops mirus*, by R. S. Funk and J. N. Packheiser 9
Amphibians of the Zoological Reference Collection, National University of Singapore, by L. M. Chou and C. M. Yang 9
Tail waving as a diversionary tactic in *Anolis carolinensis*, by M. H. Binder and R. W. Henderson 10
The first record of *Rana sylvatica* from the southern Rocky Mountains and other early collections of Arthur E. Beardsley, by G. A. Hammerson 10
Notes on reproduction in *Clemmys marmorata*, by M. Feldman 10
Toledo collection now at American Museum, by R. Conant 11
A comparison of the social behavior of *Urosaurus auriculatus* and *U. clarionensis* on the Revillagigedo Islands, Mexico, by B. H. Brattstrom 11
Two platyhelminths from *Caudiverbera caudiverbera* (Anura: Leptodactylidae) in Southern Chile, by S. Pugar 13
Amphibians and reptiles in the University of Miami reference collection, by J. C. Lee 14
POSITIONS 11
HERPETOLOGICAL HUSBANDRY
Captive reproduction of the children's python *(Liasis childreni)*, by S. Chiras 14
Courtship and copulatory behavior of captive eastern hognose snakes, *Heterodon platyrhinos*, by T. J. Nichols 16
LIFE HISTORY NOTES 17
BOOK REVIEWS
Rock Lizards of the Caucasus, by I. S. Darevskii; English translation reviewed by K. Adler 19
South African Frogs, by N. I. Passmore and V. C. Carruthers; reviewed by R. B. Humphries 20

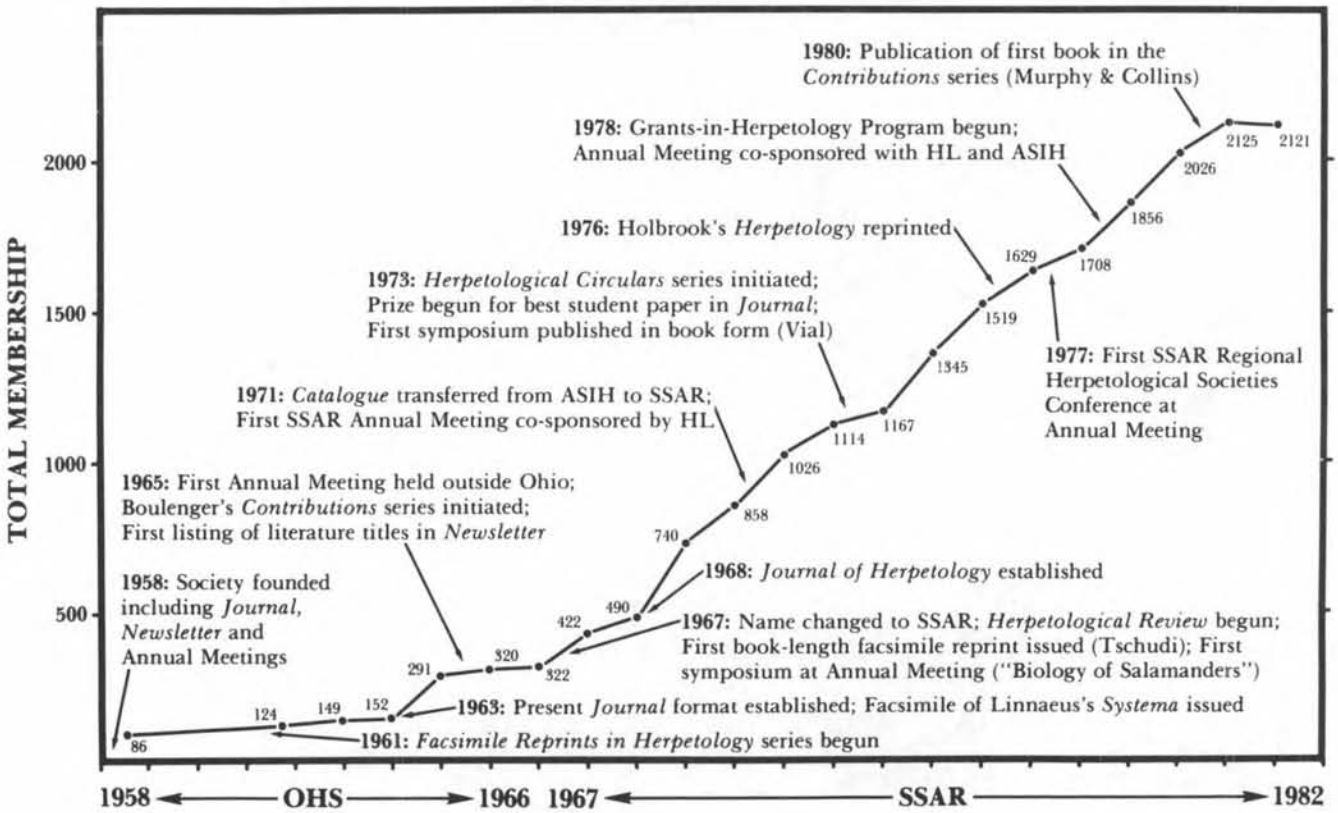
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

A MESSAGE TO THE MEMBERSHIP

This is a special year for our Society. Twenty-five years ago the society was founded as The Ohio Herpetological Society by two young amateurs and, despite this modest beginning, SSAR has grown to become the largest professional herpetological society. It sponsors innovative annual meetings of interest to a broad spectrum of persons interested in amphibian and reptile biology; supports many scientific, educational and conservation activities in herpetology; and issues six series of publications, one of the most ambitious programs of any scientific society.



SSAR has been successful in recognizing and responding to the changing and expanding needs of the herpetological community, sponsoring activities of interest not only to the professional herpetologist, but also to serious amateurs, zoo and aquarium personnel, veterinarians and to those interested in conservation. This is a tribute to the foresight of the many persons who have served the society in various leadership capacities as officers, editors, and committee members, but also to the enormous support given by the membership. A detailed history of SSAR is now being prepared by N. Bayard Green for publication, but the primary milestones are noted in the figure below.

At the Annual Meeting in August several activities will serve to mark this anniversary, including a special symposium and a commemorative poster by the noted wildlife artist David M. Dennis. Detailed information about the meeting is given elsewhere (see p. 3 in this issue). The meeting will also provide us with an occasion to honor the many hardworking officers and editors—past and present—whose dedication and imagination have ensured the success of SSAR.

To continue this progress, however, the society must attract the best possible new leadership when positions become vacant. The Nominating Committee makes every effort to identify persons willing to serve but, inevitably, some potential candidates are not known. Thus, the society encourages all persons to state their interest by letter to the SSAR President, Kraig Adler. Such persons may wish to attend the Board of Directors' meeting, this year to be held on Sunday, August 1, beginning at 10:00 AM; incidentally, Board meetings have always been open to the general membership.

In 1983 the society will meet, jointly with the Herpetologists' League, in Salt Lake City, Utah (August 7-12). The Meeting Sites Committee is presently considering invitations for 1984 and beyond. Persons interested in developing a proposal from their institution are invited first to write to the committee chair, Lynne Houck (Department of Biology, University of Chicago, 1103 East 57th Street, Chicago, Illinois 60637).

IMPORTANT EVENTS IN THE HISTORY OF THE SOCIETY

SSAR SILVER ANNIVERSARY
and
Herpetologists' League Meeting
Raleigh, North Carolina
August 1-6, 1982
First Call For Papers

Please return completed form and abstract, by *5 June 1982*, to: Ray E. Ashton, Jr., N. C. State Museum of Natural History, P.O. Box 27647, Raleigh, NC 27611.

Please *type* the following:

Author(s) (last names first); **underline** speaker:_____

_____

Institution(s): _____

_____

Speaker's address: _____

_____ Phone:_____

Speakers will receive instructions and equipment request forms from session chairman. Wayne VanDevender, Chairman of Paper Sessions; Sandy Echternacht, Chairman of Poster Sessions.

Check appropriate item:

_____Contributed paper

_____Student paper (students *only;* will be considered for HL prize)

_____Poster session (submit abstract; HL will present cash prize for best poster presentation)

_____By title only (abstract will be printed if submitted)

Type an ABSTRACT within the following space and do not exceed the margins. Use new ribbon and elite type to facilitate direct offset reproduction. Underline scientific names *only*. Follow this format: *first line*, author(s); *second line*, institution(s); *third line*, TITLE; *rest*, abstract.

SSAR 25th ANNIVERSARY MEETING

The 25th annual meeting (Silver Anniversary) of the Society for the Study of Amphibians and Reptiles will be held in conjunction with the 30th annual meeting of the Herpetologists' League, at Meredith College, Raleigh, North Carolina, 1-6 August 1982. The meeting is hosted by the North Carolina State Museum of Natural History.

Herpetological collections and research have a long tradition at NCSM. The museum came into official existence on 20 February 1879, and in December 1880 the Brimley brothers — H. H. and C. S. — arrived in Raleigh from England. They were ardent naturalists, and in 1884 began publishing papers on the state's fauna. H. H. Brimley became the museum's first curator (later director) in April 1895, and C. S. entered the employ of the Entomology Division of the N. C. Department of Agriculture in December 1919. One of C. S.'s main interests was herpetology, and among his many publications were descriptions of several new amphibians and reptiles, including the endemic aquatic salamander, *Necturus lewisi*. He also wrote the first comprehensive accounts of the local herpetozoa, assembled and published by Carolina Biological Supply Company. The museum's second director, Harry T. Davis, co-authored with C. S. Brimley a booklet on poisonous snakes of eastern North America. John B. Funderburg, fourth and current director, has published papers on the amphibians and reptiles of Florida, Virginia, and North Carolina.

In the Department of Lower Vertebrates, Chief Curator William M. Palmer has contributed papers on the North Carolina herpetofauna, including the booklet *Poisonous Snakes of North Carolina* (1974), and was a co-author of *Amphibians and Reptiles of the Carolinas and Virginia* (1980). He is currently working with the taxonomy of *Ophisaurus*, and has completed most species accounts for a book on North Carolina reptiles to be published by the museum. Alvin L. Braswell, Curator of Lower Vertebrates, has also published a number of papers, and is studying the taxonomy of an undescribed *Eurycea*, and of the lizard *Bachia* on the island of Tobago. He is engaged also in studies of local populations of *Hemidactylium, Ambystoma talpoideum, Rana areolata, Eumeces anthracinus,* and *Elaphe obsoleta*, and is working with Palmer on the state herpetological publications. In addition, Braswell directed field survey activities of a two-year, federally funded study of *Necturus lewisi*. Ray Ashton is principal investigator in this project, the results of which are now being prepared for publication as a special issue of the museum's journal, *Brimleyana*. Ashton, the museum's Director of Education, has published in herpetology, and continues studies as time allows. Windward Press recently published *Handbook of the Amphibians and Reptiles of Florida. Part I, The Snakes,* written by Ray and his wife, Pat. David S. Lee, Curator of Ornithology and Mammalogy, has published on the herpetofauna of Maryland and Florida, and John E. Cooper, Director of Research and Collections, has published on those of Maryland and Cuba, and on the cave-associated herpetozoa of Virginia, West Virginia, Alabama, and Georgia.

Program Summary

Sunday, 1 August
- Registration
- SSAR Board of Directors meeting (10:00 AM)
- HL council meeting
- Regional Society social, hosted by North Carolina Herpetological Society

Monday, 2 August
- Plenary session
- HL Distinguished Herpetologist Lecture — Thomas Uzzell, "In Praise of Common, Widespread Frogs".
- Regional Society program — "Collecting in Exotic Places"
- Contributed Paper sessions
- Social and auction

Tuesday, 3 August
- SSAR Symposium: "Molecular and Genomic Evolution of Amphibians and Reptiles," organized by David B. Wake
- Zoo Liaison program — "Meet the Grant Providers"
- Contributed Paper sessions
- "Pig Pickin'" banquet

Wednesday, 4 August
- SSAR Symposium continued, and evening open Panel Discussion
- Contributed Paper sessions
- Workshop on photographing herps
- IUCNNR Tortoise Council meeting
- Poster session — HL contest (authors available for discussion)
- Slide shows — "Herpers Past and Present" and others — David Dennis

Thursday, 5 August
- Paper session review
- Invited author question-and-answer session; Herndon G. Dowling, Chairman
- Contributed Paper sessions
- Gopher Tortoise Council, informal gathering

Friday, 6 August
- FIELD TRIP, North Carolina Sandhills

Saturday and Sunday, 7-8 August
- Conference on Plethodontid Salamanders at Highlands Biological Station. Contact Lynne Houck, Department of Biology, University of Chicago, 1103 East 57th Street, Chicago, Illinois 60634.

SSAR Symposium Topics and Speakers — David B. Wake, Coordinator

Genetic inference from electrophoretic phenotypes of proteins, an introduction — Herbert C. Dessauer, Louisiana State University Medical Center

Is the newt metapopulation model general? — Douglas E. Gill, University of Maryland

Genetic recombination in zones of secondary intergradation in amphibians and reptiles — David L. Jameson, University of Houston

The clonal nature of the *Ambystoma jeffersonianum* complex — James P. Bogart, University of Guelph (Canada)

Gene flow and population differentiation in *Ascaphus truei* — Charles H. Daugherty, University of Illinois

Genic differentiation and its correlates in the *Desmognathus ochrophaeus* and *fuscus* complexes — Stephen G. Tilley, Smith College

The correlation between reproductive isolation and genetic differentiation in eastern large *Plethodon* — Richard Highton, University of Maryland

Natural hybridization between *Bombina bombina* and *B. variegata* (Anura: Discoglossidae): a comparative study of hybrid zone structure in southern Poland and western Yugoslavia — Jacek M. Szymura, Jagellonian University (Poland)

Hybridization between subspecies of *Ensatina* — Kay P. Yanev, University of California

The recognition and relationships of species in a highly paedomorphic lineage: a biochemical study of the Mexican ambystomatid salamanders — H. Bradley Shaffer, University of Chicago

Hybridization between cryptic species of two-lined salamanders — Sheldon Guttman, Miami University

Species with extreme amounts of genetic differentiation: the species problem in *Rhyacotriton* and *Pseudoeurycea* — David B. Wake, University of California

Molecular phylogenies: frameworks for addressing major evolutionary questions — Linda R. Maxson, University of Illinois

Opportunities and limitations of microcomplement fixation techniques — Thomas Uzzell, Academy of Natural Sciences, Philadelphia

Molecular genetics and systematics of the Crocodilia — Llewellyn D. Densmore, Louisiana State University Medical Center

The neotropical colubrid snake fauna: lineage components and biogeography — John E. Cadle, University of California

Biochemical characters and the reconstruction of turtle phylogenies: relationships among batagurine genera — J. W. Sites, Jr., Texas A & M University

Patterns of karyotypic evolution in reptiles —John W. Bickham, Texas A & M University

(Title to be chosen) — Herbert C. Macgregor, University of Leicester (United Kingdom)

Mitochondrial DNA sequence analysis and reptilian systematics: applications in the lizard genus *Cnemidophorus* — Wesley M. Brown, University of Michigan

Genomic composition of reptiles: evolutionary perspectives — Ettore Olmo, University of Naples (Italy)

The significance of sex chromosomes in the evolution of salamander genomes — Stanley K. Sessions, University of California

Chromosome banding analysis in elapid snakes and its phylogenetic implications — Greg Mengden, Australian National University, Canberra City (Australia)

Open panel discussion: research opportunities and prospects. David B. Wake, moderator

Special Activities

Herpetological art, crafts, books, and para-.phernalia: show and sale

Live display of North Carolina amphibians and reptiles, with photo facilities

Special social activities

Special tours of state museums, historic sites, and other points of interest in the Triangle area

Special audio-visual presentations

Commemorative limited-edition print by David Dennis will be given to all registrants

Special commemorative limited-edition T-shirts will be on sale (send order with registration)

General Information

Pre-registration package including final call-for-papers, housing reservations, and fee schedule will be sent in April. Members of both SSAR and HL will automatically receive this information. Others may request the information by writing to the local committee chairperson.

Housing will be in air-conditioned dormitories, and only linen (no blankets) will be provided. Special rates have been arranged at a local motel for those who prefer these accommodations.

Air travel should be to Raleigh-Durham (RDU) airport. Transportation from the airport will be provided for those who pre-arrange it by returning the appropriate form in the registration package.

Local committee chairperson:
Ray E. Ashton, Jr.

A BRITTLE BUCKET CAUTION

Readers of John Legler's paean to plastic buckets (1981, Herp. Review 12(1):9-10) are cautioned that he has used them for only 5 years, and that after 5 to 9 years opaque white Saturn buckets used to store fish and reptiles at the National Museum of Natural Sciences, Ottawa, have shown a disturbing tendency to become brittle and to crack either spontaneously or when they are opened. About 1% of a population of 500 buckets in the ichthyology collection cracks spontaneously each year, and a similar or higher rate obtains in the herpetology collection. A bucket is dangerously brittle when pieces of the rings around the top of the bucket can be snapped off by hand. Buckets from some shipments are more prone to brittleness than others, but all seem to become more brittle with age. For much of this time our collections were subjected to continuous light from fluorescent lamps, and this may have embrittled the plastic.

We should not be able to explore the use of these buckets as specimen containers further, because the Ottawa Fire Marshal, at least, will not approve the storage of inflammable liquids (in our institution 45-50% isopropyl alcohol) in plastic containers, but we suggest that if they are to be used for this purpose shipments of buckets which sound brittle when they are tapped should be rejected, and that the buckets not be stacked, over-filled, or exposed to intense or prolonged light.

The first Herpetological Conference of the Socialist Countries was held in Budapest, Hungary, 25-29 August 1981. The meeting included most of the leading herpetologists from Eastern Europe and the Soviet Union and also a few colleagues from Western countries invited by the Organizing Committee, chaired by Oliver Gy. Dely. Although relatively small by comparison to herpetological meetings elsewhere, the well organized conference was not only pleasant but exceedingly important in providing the first significant occasion for contacts between several herpetologists in Eastern Europe and Russia with their counterparts in the West, contacts that will hopefully prove useful in the sharing of scientific information and also in planning future herpetological meetings such as a proposed International Congress of Herpetology. The next Conference of the Socialist Countries is tentatively scheduled for Dresden, East Germany, in 1984 (Günther Peters, organizer).

Several dozen papers covering a broad range of biological topics were presented at the Budapest meeting, as listed below; where papers were co-authored, the presenter is indicated (*). These papers will be published shortly as a volume of *Vertebrata Hungarica*, obtainable from Zoological Department, Hungarian Natural History Museum, H-1088 Budapest, Baross u. 13, Hungary.

Adler, K. (USA): Sensory aspects of amphibian orientation.

Alekperov, A. M. (USSR): Present status of rare and threatened herpetofauna in Azerbaidzhan.

***Ananjeva, N. B.** (USSR) and N. L. Orlov (USSR): The trophic behavior of snakes of the Henophidia and Caenophidia groups.

***Berger, L.** (Poland), T. Uzzell (USA) and H. Hotz (Switzerland): Systematic status of the two southern forms within the *Rana esculenta* complex.

Böhme, W. (West Germany): The problem of the hierarchy of within-species classifications.

***Brushko, Z. K.** (USSR) and R. A. Kubykin (USSR): Horsfield's tortoise (*Agrionemys horsfieldi* Gray, 1844) and its rational utilization in Kazakhstan.

Ckhikvadze, V. M. (USSR): On the finding of fossil Cryptobranchidae in the USSR and Mongolia.

Darevsky, I. S. (USSR): Unisexuality in the Reptilia: results and projects.

Darevsky, I. S. (USSR) and *L. A. Kupriyanova (USSR): Rare males in the parthenogenetic species *Lacerta armeniaca* Méhely.

Dely, O. Gy. (Hungary): Morphological variation in the Balkan wall lizard (*Lacerta taurica* Pallas).

***Dely, O. Gy.** (Hungary) and G. Stohl (Hungary): Head shields and phylogenetic relationships in the Lacertidae.

Engelmann, W.-E. (East Germany): Serological studies on taxonomy of the genera *Lacerta* and *Gallotia*.

Freytag, G. E. (East Germany): Concerning *Pachytriton brevipes* Sauvage.

***Gans, C.** (USA) and G. C. Gorniak (USA): Muscle architecture of frog tongues; a neglected characteristic.

Garanin, W. I. (USSR): Urbanization and the herpetofauna.

Gasc, J. P. (France): The mechanism of crawling in *Amphisbaena alba* (Amphisbaenidae, Squamata).

Günther, R. (East Germany): Results of experimental crosses between waterfrogs from Europe and Central Asia.

Hodrová, M. (Czechoslovakia): The genus *Pliobatrachus* from Czechoslovakia.

Itämies, I. (Finland): On the food of *Rana arvalis* Nilss. in central Finland (presented by G. Kramer).

Jurcsák, T. (Romania): New findings of Sauria from the Mesozoic of Romania (presented by A. Embey-Isztin).

Korsós, Z. (Hungary): Field observations on two lizard populations (*Lacerta agilis* L. and *L. viridis* Laur.).

Kramer, E. (Switzerland): Systematic questions on the European snake fauna.

Langerwerf, B. A. W. A. (Netherlands): Reproduction of several Asiatic *Agama*- species in terraria.

***Lukina, G. P.** (USSR) and T. F. Krawtschenko (USSR): Ecological aspects of the desert runner lizard *(Eremias)* in the northern Caucasus.

Moody, S. M. (USA): Phylogenetic origins and relationships of the terrestrial genera *Agama, Phrynocephalus* and *Uromastyx* within the family Agamidae.

Peters, G. (East Germany): Phylogenetic problems of Lepidosaurian systematics.

Roček, Zb. (Czechoslovakia): A new view on the basic phylogeny of frogs.

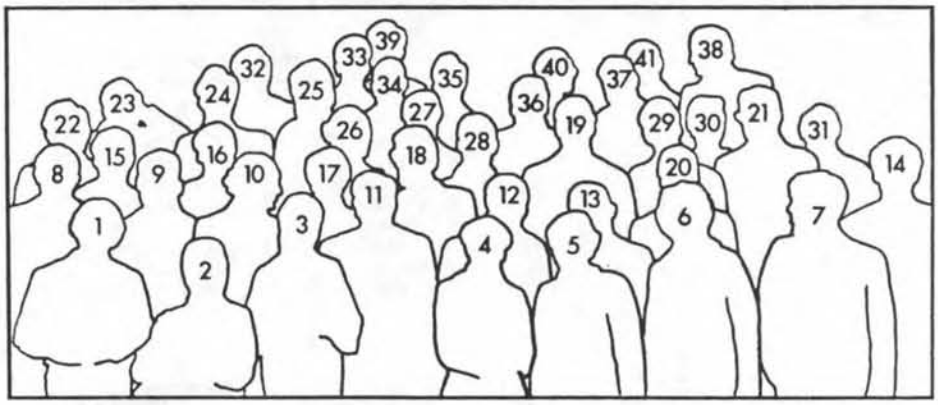
Rustamov, A. K. (USSR) and *S. Shammakov (USSR): Biotopic distribution and the numbers of reptile species in the flat lands of Turkmenistan.

Sharpilo, V. P. (USSR): An historical look at the origin of the Palearctic helminth fauna of reptiles.

***Špinar, Zd.** (Czechoslovakia) and L. P. Tatarinov (USSR): A new frog from the Upper Cretaceous of Gobi; its significance for the systematics, phylogeny and paleobiogeography of Anura.

Szczerbak, N. N. (USSR): Characteristic features of the herpetogeographic organization of the Palearctic province.

Szymura, J. M. (Poland): Hybrid zones between *Bombina bombina* (L.) and *B. variegata* (L.) in Europe.



Tatarinov, L. P. (USSR): The significance of paleontology for herpetology.

Vancea, Şt. (Romania), J. E. Fuhn (Romania) and M. Borcea (Romania): Morphological investigations of *Vipera berus* populations from the central highlands of Moldavia, East Carpathia and Transylvania (presented by E. Kramer).

Besides the technical sessions there was a one day field trip to Lake Balaton during which the group visited the famous Biological Institute (Tihany) and the University of Agriculture (Keszthely).

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $29.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $53.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

REPRODUCTION AND FEEDING IN *Eridiphas slevini* (SERPENTES: COLUBRIDAE)

Since its discovery in 1921 by Joseph Slevin, *Eridiphas slevini* Leviton and Tanner (1960), has remained one of the rarest snakes known to occur on the Baja California peninsula. It is presently represented in collections by about 20 specimens. Aside from its general distribution and apparent differentiation into an insular subspecies (Ottley and Tanner, 1978), little is known of its biology. This note presents the first record of its reproduction.

On 24 July, 1979, a gravid *Eridiphas slevini* (KU 185647; Fig. 1) was collected from a date palm *(Phoenix dactylifera)* grove ± 1 km N of San Ignacio, Baja California Sur, México. The specimen was coiled inside the moist center of a decaying, prostrate palm trunk. The ground around the trunk was covered by small pools of standing water. Several *Hyla regilla* and an adult *Pituophis melanoleucus* were also found at this site.

On 26 August, the snake was placed in a 25 gal terrarium having 8-10 cm of coarse sand on the bottom with bark strips and rocks providing cover. Two eggs were found beneath a piece of bark on 9 October (average measurements: medial width = 10.0 mm; length = 52 mm; weight = 3.6 gms). The female weighed 26 gms after egg laying. The eggs were thin-shelled and leathery in texture with a distinct kidney shape. Both eggs had a diffuse pink medial area with slightly tapering, cream-colored ends. The eggs were incubated in a 1 gal glass container to which a layer of moist vermiculite had been added in the manner described by Campbell (1972). The eggs were checked daily during incubation and the container was opened periodically when condensation became excessive. Air temperature fluctuated between 20° C (68° F) and 29° C (84° F) during incubation. No measurable changes in egg dimensions occurred during incubation.

On 5 November the air temperature dropped to 15° C (58° F) for several hours, and on 7 November the eggs were wrinkled. Dark spots appeared on the eggs a few days later. On 11 November, 64 days after deposition, the eggs were presumed dead and were opened. Both eggs contained a well developed embryo with considerable yolk. Morphological characteristics of the embryos and adult female are within the range given by Ottley and Tanner (1978), for their specimens from San Ignacio (Table 1). Head and body scales of the embryos were well developed, although pigmentation was minimal and pattern development was completely absent. Pigmentation was limited to a single, diffuse lateral stripe involving the 3rd and 4th scale rows and the 4th and 5th scale rows of the female and male embryo, respectively. The skin was translucent. Cranial ossification was not complete; the brain of both embryos being exposed dorsally. The hemipenes were everted in the male and umbilical slits were present in both embryos.

The extreme elongation of the eggs of *Eridiphas* prompts comparison with other closely related genera. Leviton and Tanner (1960), stated that *Eridiphas*, on the basis of "intermediate" morphological characteristics, represented a relict of an early ancestral stock from which *Hypsiglena* and *Leptodeira* subsequently diverged. A comparison of clutch size and egg dimensions of *Hypsiglena, Leptodeira*, and *Eridiphas* is presented in Table 2. The length of *Eridiphas* eggs is striking, especially when compared with other closely related colubrids. The relationship that exists between clutch size and egg dimensions may partially explain this, but whether this is due to genetic or more proximal influences on these reproductive parameters, must await further records of reproduction in this species.

The *Eridiphas* refused food items such as juvenile *Mus musculus* and *Eumeces fasciatus* prior to laying. An adult *Phyllorhynchus decurtatus* and *Chilomeniscus cinctus* which shared the terrarium with the *Eridiphas* were not disturbed. Food items, prey size, and feeding dates were: *Coluber constrictor erythrogaster* (T.L. = 15 cm; 13 Sept.), *Tropidoclonion lineatum lineatum* (T.L. = 10 cm; 25 Sept.), and *Thamnophis sirtalis parietalis* (T.L. = 13 cm and 12 cm; 10 Oct. and 30 Oct., respectively).

In each instance, feeding behavior was similar. The *Eridiphas* sensed the presence of potential prey by rapid tongue flicking. It would move from its retreat and apparently through the use of visual and chemosensory cues, proceed to follow the prey. It was sensitive to slight movements of the prey during this pursuit phase. When within a few centimeters of the head of the prey, the *Eridiphas* struck, usually seizing it behind the head. On several occasions, the strike missed the prey. Upon making a capture, the *Eridiphas* worked the head of the prey to the back of the mouth and retained it there for several minutes before swallowing. Possibly, envenomation occurred during this interval. Constriction of the prey never occurred, although the *Eridiphas* often dragged the prey about the terrarium by its head, using objects such as rocks and bark to gain a purchase on the prey prior to swallowing.

We wish to thank Jonathan A. Campbell, Dr. William E. Duellman, Dr. Henry S. Fitch, and Nancy L. Zuschlag for critically reading the manuscript and offering helpful comments. We also thank Ken Stockton for assistance in the field and Hank Guarisco, Animal Caretaker, University of Kansas, for providing food items and caring for the snakes. Scientific collecting permits for México were issued to JRO by the Dirección General de la Fauna Silvestre.

PARASITIC NEMATODES, *Kalicephalus willeyi*, IN A SRI LANKAN BLIND SNAKE, *Typhlops mirus*

Worm snakes of the family Typhlopidae are poorly-known ecologically, partly because their small sizes and fossorial habits usually preclude collection of large series, and partly because identification of specimens is notoriously difficult. In reviews of snake diseases, neither Reichenbach-Klinke and Elkan (1965) nor Page (1966) mentioned blind snakes.

In February 1978, the senior author received several live typhlopids from Sri Lanka. One female snake, collected 17 January 1978 at Illukumbura, Kandy, Marrichikadda, orally expelled three nematode worms when preserved on 2 March. We identified this snake as *Typhlops mirus* Jan, since it agreed with Taylor's (1947, 1950) accounts of this uncommon species in having: a subocular; eye not apparent; 18 longitudinal scale rows around body; transverse scale rows 337 on body and 15 on tail; no terminal spine; ventral 3 scale rows light-colored, with portions of two adjacent lateral rows on each side light but becoming dark dorsally, and all of dorsum very dark brown (in life); total length (after preservation) 140 mm, tail 5 mm.

The nematodes were fixed and then cleared in lacto-phenol. We identified these worms as *Kalicephalus willeyi* von Linstow (Diaphanocephalidae) from Schad's (1962) diagnosis of this species in having: face flat; esophageal bulb wider and set off from esophageal neck; males almost invariably absent (our three specimens are females).

This is the first record of a nematode from *Typhlops mirus*, a snake which is endemic to Sri Lanka, and a new host record for *Kalicephalus willeyi*. Yamaguti (1961) and Schad (1962) reported *K. willeyi* from a variety of Oriental boid, colubrid, viperid, and elapid snakes, and from the typhlopid *Ramphotyphlops braminus* (Daudin) (formerly placed in the genera *Typhlops* or *Typhlina*).

The snake specimen is preserved in the senior author's collection (RSF 3676), and the nematodes have been deposited in the National Parasite Collection (U. S. Natl. Mus. Helminth Coll. No. 75513).

ACKNOWLEDGMENTS

We thank: W. L. E. de Alwis, B. Fernando, and J. Samarakoon for providing the snake; D. E. Hahn for confirming the identity of the snake; J. R. Lichtenfels for accessioning the worms; and L. E. Brown, D. E. Hahn, and H. W. Huizinga for critically reading the manuscript.

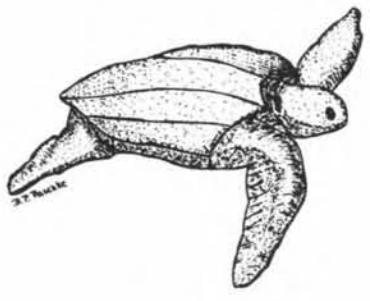
AMPHIBIANS OF THE ZOOLOGICAL REFERENCE COLLECTION, NATIONAL UNIVERSITY OF SINGAPORE

The Zoological Reference Collection of the National University of Singapore has been maintained by the Department of Zoology since 1972 when it was taken over from the National Museum (formerly Raffles Museum) of Singapore.



The amphibian collection contains over 1200 specimens belonging to 21 genera. Three paratypes are represented in the collection and they are *Amolops kinabaluensis* Inger 1966, *Rana nitida* Smedley 1931 and *Rana tweediei* Smith 1935. The majority of the collection originated from the Southeast Asian region and were obtained between 1890 and 1981. The species within the collection are fairly representative of the amphibians of this region. A list of species is available upon request.

At present, the collection is housed temporarily at the campus of the Nanyang Technological Institute. A permanent site within the new campus of the National University of Singapore has been identified and will be ready late next year. The collection is being expanded through mutual exchange and as soon as it is located within the new building, a more aggressive improvement programme can be embarked upon.

Researchers are most welcome to examine the collection should they be in Singapore at any time. Inquiries regarding the collection should be sent to Mrs. Yang Chang Man whose address appears below.

We would like to thank Dr. H. K. Voris and Dr. R. F. Inger of the Field Museum of Natural History, Chicago, for their time spent on examining some of the specimens and their invaluable comments on the collection.

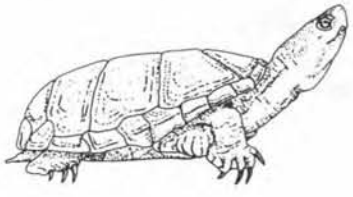
TAIL WAVING AS A DIVERSIONARY TACTIC IN *Anolis carolinensis*

Ballinger (1973) hypothesized that the tail of the iguanid lizard *Anolis carolinensis* functions as a balancing organ, and he presented experimental evidence to support his hypothesis. Here, we suggest a possible cofunction for the tail of *A. carolinensis*.

Over the past three years, we have seen hundreds of anoles stalked by saurophagous snakes (primarily arboreal species). Although tree snakes in general, and attenuate-snouted species (*e.g. Oxybelis*) in particular, rarely miss seizing their prey on the first strike (Henderson and Binder, in prep.), we have witnessed some unsuccessful strikes. Many saurophagous snakes are diurnal, movement-oriented predators that seemingly lose visual contact with a lizard that remains motionless. On a number of occasions, we have observed anoles, that were apparently aware that a potential predator was near, become motionless except for waving their tails back and forth. The tail was raised above the ground and then switched and undulated back and forth, sometimes hitting the ground. On several occasions, this tail movement provided the necessary stimulus for the snake to regain visual contact and make a successful strike at the lizard's body, but in other instances the waving tail acted as a diversion. In those cases, a snake would strike at the waving tail and the lizard would run from the snake, usually with its tail still intact. Since the lizards were confined, it was only a matter of time before the snakes located them again, but in nature the missed strike would probably have given the anoles time to seek a protective shelter.



Perhaps the reason Ballinger (1973) found so few *A. carolinensis* with regenerated tails was because such anoles lack their diversionary organ, and so are more susceptible to predation.

THE FIRST RECORD OF *Rana Sylvatica* FROM THE SOUTHERN ROCKY MOUNTAINS AND OTHER EARLY COLLECTIONS OF ARTHUR E. BEARDSLEY

In 1946, Maslin collected 17 specimens of *Rana sylvatica* in north-central Colorado (Maslin 1947). In 1947, Baxter reported *R. sylvatica* from southern Wyoming. Although these were the first records for the disjunct *R. sylvatica* population in the southern Rocky Mountains, an unreported specimen was taken nearly 50 years earlier.

The University of Northern Colorado (UNC) in Greeley formerly housed an early important collection of Colorado amphibians and reptiles. Unfortunately, this collection apparently was destroyed in a fire. However, a register of specimens bearing the title "Museum Register 3, Colorado State Normal School" (an old name for UNC) still exists in good condition. In the register is listed a *Rana cantabrigensis* (= *R. sylvatica*) collected by A. E. Beardsley near Chambers Lake on 26 August 1898. Chambers Lake is in north-central Colorado and has been the site of many *R. sylvatica* collections since 1950.

Many specimens collected by Beardsley throughout Colorado are listed in the museum register. Most were recorded by Ellis and Henderson (1913) but *R. cantabrigensis* was not included. Perhaps the accuracy of its data was doubted, but today there is no reason for doubt; *R. sylvatica* can still be found in that vicinity. Beardsley was primarily an invertebrate zoologist, and perhaps for that reason failed to publish the record or to convince others of its validity.

Many of Beardsley's amphibian and reptile discoveries in Colorado took many years to be confirmed by additional specimens. The second specimen of *Bufo debilis* was found 81 years after Beardsley's first listing. The second specimens of *Sonora episcopa* and *Diadophis punctatus* came 75 and *ca.* 50 years after the first ones. Thus, several doubtful records of Beardsley's early collections have since been validated.

Corroboration of the accuracy of Beardsley's early amphibian and reptile listings from Colorado is most pertinent to his as yet unconfirmed disjunct records (see Stebbins's 1966 maps) of *Storeria* (1883) and *Hyla arenicolor* (1886) from Las Animas Co., Colo. (Ellis and Henderson 1913). Beardsley's excellent reliability for other species strongly suggests that these species too at least formerly inhabited southeastern Colorado. Intensive field work is needed to clarify their status.

I thank Dr. James Fitzgerald for making the museum register available to me and Dr. Hobart M. Smith for his helpful comments on the manuscript.

NOTES ON REPRODUCTION IN *Clemmys marmorata*

From June 30 to July 24, 1978, four female Western pond turtles *(Clemmys marmorata)* were captured between 7 and 11 a.m. on the land while apparently attempting to find suitable nesting sites along the Umpqua River near Roeburg, Douglas County, Oregon.

They varied in carapace length from 16.0 to 17.1 cm. Each was injected with oxytocin (into the oviduct) to induce egg laying. Clutch sizes were 4, 7, 9 and 9 eggs. These clutch sizes are within the range of 3-11 eggs reported by Ernst and Barbour (1972). One egg broke. Of the remaining 28 eggs, 10 were incubated on saturated vermiculite and 18 on a screen over a water bath heated to 30° C. Air temperature during incubation varied between 25° and 30° C.

None of the eggs on the vermiculite hatched and only two showed any development. Of the 18 on the screen, 13 hatched and only 2 showed no development. Hatching time was 73-80 days.

Many of the hard shelled eggs on the saturated vermiculite split open early in development. Apparently they absorbed more water than they could contain (Plummer, 1976).

Since the summers along the Umpqua River near Roseburg are hot and dry it makes sense that the eggs of *Clemmys marmorata* would evolve to absorb all the water they could. Hence, in a wet environment, they can literally explode from excess internal pressure (Claessen, 1980). This is in contrast to eggs of *Kinosternon subrubrum* and *Sternotherus odoratus* which were also incubated on saturated vermiculite and developed normally. These eggs, from species living in areas with higher summer rainfall, do not tend to absorb as much water (Lynn and von Brand, 1945).

It was also noted that the hatchlings (from 2.5-2.9 cm in carapace length) did not leave the egg if the temperature exceeded 27° C. But, once moved to a cooler environment, they broke free of the egg within 2-3 hrs. This

may be adaptive since a hatchling exposed to the drying heat of the summer sun would quickly dehydrate and die. Since eggs of *Clemmys marmorata* are frequently laid far from the water (Storer, 1930) such a mechanism could have great survival value.

TOLEDO COLLECTION NOW AT AMERICAN MUSEUM

Through the courtesy of the Board of Directors of the Toledo Zoological Society and its Executive Director, William V. A. Dennler, the collection of approximately 3,000 preserved amphibians and reptiles, formerly housed at the Toledo Museum of Health and Natural History (TMS), was recently transferred to the Department of Herpetology at the American Museum of Natural History (AMNH) in New York City. It will be available for study as soon as it is catalogued and cross-indexed at the latter institution, with which I have been a Research Associate since 1948.

Because of serious staff limitations, the Toledo Zoo was forced to adopt a restricted policy. No specimens could be borrowed, although herpetologists were permitted to examine them on site. The material was kept permanently in a dark, windowless basement room, which effectively prevented serious fading. Attrition, chiefly a result of deterioration of rubber jar rings used on the storage bottles, was minimal. A number of specimens, which a few years ago were lent to Toledo University and some of the city's high schools as teaching aids, were retrieved by Dennler before the transfer was made to New York. In general, the collection is in excellent condition despite the fact it had been largely untouched for 46 years. It was curated in part during 1977 by Gregory O. Vigle (Herp. Rev., 9(2):48-49) through the cooperation of Philip C. Skeldon, Executive Director Emeritus.

The material was assembled from 1929 to 1935 while I was associated with the Toledo Zoo. The bulk of it is from Ohio localities, and it served in large part as the basis for the text and distribution maps in the "Reptiles of Ohio" (Amer. Midland Nat., 1938). Through the kindness of my superiors, I was permitted, during spring and early summer weekends and occasionally in autumn, to take an extra day, in addition to my one day off each week, in order to go afield. My companions and I shared the expenses, which were largely for gasoline (then under 25 cents a gallon) and meals (with care one could get by on a dollar a day!). My "Chevy" provided transportation. Personnel varied from trip to trip and, although I am indebted to everyone who helped, there were four who participated most frequently and therefore made the largest contributions to the driving, hiking, climbing, and rock turning. They were, David D. Delzell, Barney Gardner, Malcolm K. Murphy, and Homer Percival. Repeatedly we visited all parts of Ohio and accumulated a varied collection that would be impossible to duplicate today. Destruction of habitats, pollution, and other factors have taken their toll.

For making the transfer possible, I thank the officials at the Toledo Zoo and Thomas D. Nicholson, Director, and Charles W. Myers, Chairman of the Department of Herpetology, respectively, of the American Museum of Natural History. Also, I am grateful to Richard G. Zweifel, Curator, and George W. Foley, supervisor of the collection in New York, who drove to Toledo and returned with a truck load of specimens.

Inasmuch as there no longer is a collection in Toledo, TMS should be deleted from the list of museum "acronymys" (Herp. Rev., 11(4):93-102).

POSITIONS

HERPETOLOGIST
UCLA

The Department of Biology invites applications at the Assistant Professor, or more senior, level. The position is funded for the academic year 1982-83. We anticipate that it will be made permanent. Teaching will include a one-quarter course on the biology of reptiles and amphibians, participation in a team-taught lower division course, and the offering of an advanced course or seminar.

Applications are due by April 1 and should include a curriculum vitae, copies of recent publications, a description of research goals, and the names of four individuals from whom we may request letters of appraisal. Send to:

G. A. Bartholomew, Chair
Herpetology Search Committee
Department of Biology
University of California
Los Angeles, California 90024 ●

A COMPARISON OF THE SOCIAL BEHAVIOR OF *Urosaurus auriculatus* AND *U. clarionensis* ON THE REVILLAGIGEDO ISLANDS, MEXICO

The Islas Revillagigedo consist of a group of four volcanic, oceanic islands located between 350-650 km southwest of the tip of Baja California, Mexico. The islands, in order of increasing size, are Roca Partida, San Benedicto, Clarion, and Socorro. The herpetofauna consists of sea turtles (*Chelonia mydas* which breeds on Socorro and Clarion, and one record of breeding of *Caretta caretta* on Clarion), an endemic species of snake (*Masticophis anthonyi* on Clarion) and two endemic lizards (*Urosaurus auriculatus* on Socorro and *U. clarionensis* on Clarion Island. In 1955, I published on the general natural history of these reptiles based on a trip in 1953 (Brattstrom, 1955). I have since been on the Revillagigedo Islands several times, largely associated with studies on the repopulation of Barcena Volcano, 1952, on San Benedicto Island (Brattstrom, 1963).

I have collected additional information on these reptiles on the several trips (including specimens, skeletons, and live animals for chromosome studies all of which are in the Los Angeles County Natural History Museum or Calif. State University, Fullerton collections). I here report on the differences in the social behavior of the two species of *Urosaurus*.

Urosaurus auriculatus

The adult male Socorro Island lizard is, when warm, a brilliant bright blue lizard. The females are smaller than the males and not as blue. The lizard occurs at all elevations on the island, from beaches and lava flows at sea level to near the top of Mt. Evermann at 1130 m. It is a very wary lizard as its only predator is the Socorro Red-tailed Hawk. While the lizard occurs sparcely on rocky slopes and cliffs and near the edges of barren lava flows, it is much more abundant in the heavily vegetated arroyos on the south side of the island and in the heavy *Ficus, Prunus,* and *Guitardia* forests of the northern wetter slopes of the island. Inactive individuals can be found under logs, bark of dead trees, rocks, and coral rubble. Juveniles appear to be most common in open and marginal areas while juveniles and adults are found together in forested areas. The young are the most wary and the adult males the least.

The lizards seem to have a loose hierarchy and they seem to forage by wandering about thru the forested area. In one 6 x 6 m plot, for example, a series of logs occurred beneath a bunch of vine covered *Guitardia* shrubs. Portions of two logs were in full sun while the rest were in shade or semi-shade. As lizards crawled into the sunny spot, they would stop and bask. Within an hour I collected 14 lizards from these two spots on those two logs. It

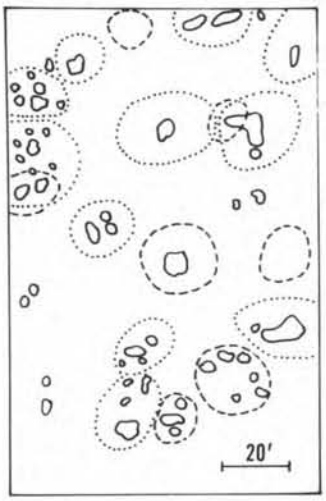
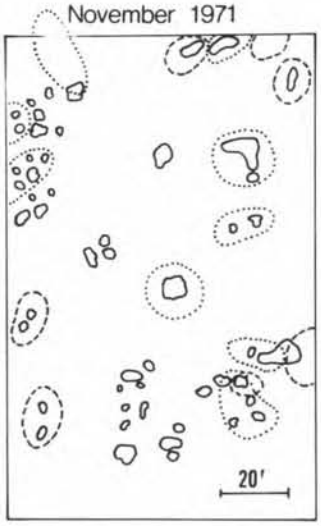
seemed that the lizards were just wandering thru the area, when one passed on (or was caught), another would enter the area. In another site, a 5 m tall fig tree at Academy Bay, I collected from this one tree and the dead branches at its base, two large males, two large females, and many small juveniles. I returned to the same tree an hour later and collected about the same number of lizards. The impression was that the lizards were just passing thru. They would explore the tree and branches searching for food, then move on. On two occasions, I saw a large male make an assertion display. I saw no chases or other displays. Hence there seemed to be no exclusions or fighting, suggesting a passive hierarchy based more or less on size and sex.



Urosaurus clarionensis

The males of this lizard found only on Clarion Island are bright green when warm. The females are smaller than the males and are brown above with some green on the sides; juveniles are mostly all brown. Clarion is the oldest of the four islands and instead of heavy lava flows has a cinder cone base with a large number of well rounded lava boulders strewn about. The vegetation consists of fairly low grasses and *Opuntia* cactus occurring over most of the island and some shrubs to 3 m high on some of the higher (335 m) parts of the island. The lizards are found at all elevations. Juveniles only are found on and about coral rubble on the upper beaches. Juveniles and adults are found elsewhere on the islands. The lizards are not at all wary and are very conspicuous as they bask on top of exposed boulders. The only predator on this lizard is the Clarion Island Racer. Perched on top of boulders, the lizards apparently can easily see approaching racers.

These lizards are clearly territorial, defending by short quick push up displays and chases. In March 1953, I observed lizards in a large (26.8 x 44.2 m) study plot on the south side of the island (Brattstrom, 1955). The entire plot, with its low vegetation and large boulders could be seen from any vantage point outside the plot. I walked around and thru the plot for two hours until I was convinced I had located every lizard (indeed almost all of the lizards could be seen at any one time from certain places). In March of 1953, 11 males and 6 females were observed on the plot. On November 9, 1971, I sampled the same plot and counted 9 males and 7 females (Fig. 1). So, while the two counts were 18 years apart, the numbers of lizards on the plot were essentially the same (16 in 1971, 17 in 1953). This would suggest that the population levels on Clarion are fairly stable.



The lizards observed were territorial, with males having mutually exclusive territories and females having either exclusive territories or those which overlapped or were closely adjacent to that of males (Fig. 1). A territorial system is probably facilitated by the more or less evenly distributed large boulders found about the island. In one situation, however, the topography seemed to have induced or allowed a hierarchy to form. At the east end of the southern beach (Sulphur Bay) a large rock (3 x 9 m and 6 m high) had on and about its base, 3 large adult males, 2 adult females, and several juveniles. Maybe the size of this rock and its many cracks and crevices allowed for more lizards to occur on it. Maybe a hierarchy did not occur and the territories were too subtle for me to observe.

March 1953

---- Male
..... Female
—— Rocks

November 1971

Summary

It would thus appear that because of abundance of two major resources, food and dense vegetation, plus the need to escape from the Red-tailed Hawk, a hierarchical social behavior has developed on Socorro Island. The wide distribution of one resource (rocks) and perhaps a more limited food supply requires that a territorial social system predominate on Clarion Island. This in turn allows for vantage sites from which to escape the predacious racer. The territorial system may allow for a fairly stable and fairly equally distributed population. The hierarchical system would allow for a larger population of lizards to occur in areas of Socorro Island where food is more abundant.

TWO PLATYHELMINTHS FROM *Caudiverbera caudiverbera* (ANURA; LEPTODACTYLIDAE) IN SOUTHERN CHILE

Caudiverbera caudiverbera is an aquatic frog which ranges in Chile between Coquimbo Province and Llanquihue Province (Cei, 1962).

There are few data about parasites of this frog; previously only the tapeworm *Ophiotaenia noei* (Proteocephalidae) (Noé and Lira, 1946) and the trematode of the urine bladder *Gorgoderina valdiviensis* (Gorgoderidae) (Puga, 1979) have been reported.

New parasitological observations of *C. caudiverbera* are presented here, which are based on 36 adult frogs of both sexes collected in Valdivia city (Southern Chile). These data are compared with the observations presented by Noé and Lira (1946), to frogs collected in Santiago Province (Central Chile).

Of the 36 frogs examined, 21 (58.3%) were infected with *O. noei* and 3 (8.3%) with *G. valdiviensis*. In Table 1, the percentages of both parasites infecting males and females of *C. caudiverbera* are presented. Only the females were parasitized with the fluke *G. valdiviensis*.

TABLE 1. Platyhelminthe infection in 36 specimens of *Caudiverbera caudiverbera* from Southern Chile.

	Host sexes					
Platyhelminthes	Males (N=19)		Females (N=17)		Total (N=36)	
	Infected		Infected		Infected	
O. noei	10	52.6%	11	64.7%	21	58.3%
G. valdiviensis	0	0	3	17.6%	3	8.3%

TABLE 2. Monthly variation in *O. noei* and *G. valdiviensis* infection in *Caudiverbera caudiverbera* from Southern Chile.

	Number of frogs				
		with *O. noei*		with *G. valdiviensis*	
	examined	N°	%	N°	%
July	1	1	100	0	0
August	2	2	100	2	100
September	8	7	87.5	0	0
November	12	2	16.6	1	8.33
December	13	8	61.5	0	0

The highest degree of parasitism was observed in a female (13 cm snout-vent) contained 14 tapeworms, and a male (9 cm snout-vent) containing 9 specimens of *O. noei*. The mean tapeworm content observed was 4.5 (range: 1-4). One female of *C. caudiverbera* held 7 flukes.

Table 2 shows the monthly variation of *O. noei* and *G. valdiviensis* in *C. caudiverbera*. *G. valdiviensis* was not reported by Noé and Lira (1946) in the urine bladder of this frog; however, in different parts of Santiago Province (San Antonio, and Santiago Department) they found that 38 (50%) of 75 examined frogs were parasitized by *O. noei*. The degree of parasitism found in Southern Chile was 58.3%.

AMPHIBIANS AND REPTILES IN THE UNIVERSITY OF MIAMI REFERENCE COLLECTION

Catalogued specimens of amphibians and reptiles in the reference collection of the University of Miami (UMRC) presently number 7,654, representing 50 families, 206 genera, and 512 species (Table 1). The bulk of the collection consists of specimens obtained by J. A. Weber during the 1920's - 1940's and donated to the University of Miami in 1947. In the summer of 1952, L. N. Bell and Albert Schwartz merged the Weber collection with the small reference collection of the University.

Three-quarters of the specimens (75.9%) are from the eastern United States. Especially well represented are the genera *Desmognathus, Notophthalmus, Plethodon, Scaphiopus, Bufo, Acris, Hyla, Rana, Anolis, Nerodia,* and *Thamnophis.* The balance of the collection consists of specimens from Mexico, Central and South America (12.7%); the Western United States (7.2%); the Caribbean (2.8%); and the Old World (1.3%).

Although small, the collection may be of interest to the herpetological community because a number of species common to the eastern United States are represented by large series, and because the collection contains several species that are uncommon in collections (*e.g., Andrias japonicus, Alytes obstetricans* with eggs, *Hemiphractus probocidius*). In addition, the collection is of historical importance in that it contains samples of several introduced species (*e.g., Anolis distichus, A. sagrei, Osteopilus septentrionalis*) that were collected early in the process of colonizing southern Florida. Finally, the collection contains the holotype and a paratype of *Coluber constrictor haasti* Bell, and five paratypes of *Leiocephalus carinatus hodsoni* Schmidt.

Some of the older material is badly formalin-burned, but most specimens are well preserved, and nearly all bear locality data. All are stored in 70% ethanol except tadpoles, which are stored in 10% buffered formalin. The specimens are cross referenced taxonomically, but no geographic file exists.

A listing of specimens, complete as of 13 March 1981, is available upon request.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

CAPTIVE REPRODUCTION OF THE CHILDREN'S PYTHON, *Liasis childreni.*

INTRODUCTION

L. childreni is a small python indigenous to Australia. It is commonly found in savannah areas characterized by extreme day/night temperature fluctuations of 1-30 C (M. Moyle: pers. comm.). Various observations of successful breeding have been recorded for *L. childreni.* Ross (1973) reported two clutches of eggs from breeding during a period of shortened photocycle and variable day/night temperatures. In a compiled report, Ross (1978) indicated temperatures of breeding as low as 21.1 C during the months of April-August. R. Cauble (pers. comm.) reported breeding at 26.7-29.4 C and an egg incubation time of 45 days. The results of this study follow a somewhat similar pattern.

A description of the prerequisite conditions to breeding of thermocycle, relative humidity, nutrition and photoperiod are included. Specific notes on breeding behavior, oviposition, artificial incubation and hatchlings are also included.

MATERIALS AND METHODS

Two adult *L. childreni* were acquired from a private keeper in May 1978. Collection data are unknown. The *L. childreni* were probed (Laszlo: 1975) and proved to be a sexual pair.

The male weighed 476 g and measured 1041 mm in total length. The female's weight was recorded at 402 g and total length was 990 mm.

The specimens were housed separately in 35 liter aquaria. Newspaper was used as substrate. A piece of cork bark was placed in each cage to provide a hiding place. The gravid female was moved to a large fiberglass cage (914 x 457 x 302 mm) with basking and thermal gradient facilities to allow her to seek optimum conditions for embryonic development.

The snakes were maintained in a room where the average temperature was 28 C day and 24 C night. During August and September the day/night temperatures were more variable at 30 C/18 C. The nightly lows were achieved by blowing cooler outside air into the room through a window by fan. Temperature was stabilized after these months at 28-24 C.

Room humidity was relatively constant year round at 40-50 percent. A room humidifier runs during the dry winter months to maintain the desired level. Cage mistings were not utilized. A 101 ml water bowl was present at all times. This provided both drinking water and a source for cage humidity. Relative humidity and temperature were measured with a Bendix model 594 Hygrothermograph.

Both *L. childreni* were fed at 7-10 day intervals. The female was fed larger meals in an attempt to increase her weight for breeding. The male was kept comparatively thin. No vitamin supplements were used.

Cage lights were not utilized. Twenty watt fluorescent Vita-lite tubes from adjacent cages ran from 0600-1800 h. Two high-intensity, 40 watt Vita-lite tubes ran on the ceiling from 1000-1600 h.

The pair were separated whenever breeding activity subsided for more than 48 h. Forty-eight to 72 h later the male was reintroduced to the female's cage and copulation occurred within 24 h on most occasions. Twenty-five separate instances of breeding were noted from 25 October to February 1979.

The eggs were incubated in a still air incubator at 31 C, with 100 percent relative humidity. The incubator was a wooden unit covered with styrofoam. Non-automatic heat tape was stapled to the inside bottom and was plugged into a wafer-type incubator thermostat mounted at egg level. The egg box was a covered plastic shoe box which contained potting soil. A minimum-maximum thermometer was set in the egg box to check for possible variances in temperature. The box maintained a constant temperature in relation to the incubator itself, which varies during the heating and cooling process of thermostat operation. An aluminum pan was set on the heat tape and filled with pea gravel. Water was added to the pan to provide humidity. The pan also served to disperse heat of the heat tape evenly throughout the incubator and reduce the possibility of hot spots. The eggs were placed on top of the potting soil for easy viewing during the daily checks.

The neonates were individually housed in plastic shoe boxes. Paper towel substrate was used. The cage was placed over a single length of heat tape. A 50 ml water bowl was placed over the tape, inside the cage. The resultant environment for the hatchlings was warm and humid.

RESULTS

The male was introduced to the female's cage 24 October 1978. Copulation was noted the next day at 0915 h and continued until 1800 h. Courtship was never observed. The male was always positioned next to the female with his tail under hers, with both tails resting on the cage floor. They maintained this position without motion until separation occurred, 1-9 h later. The lowest temperature at which copulation occurred was 20 C and the highest was 26.7 C ($\bar{x}$ = 22.8 C). Relative humidity ranged from 40-50 percent ($\bar{x}$ = 44.48 percent).

The female appeared gravid in mid-January 1979. She first refused food on 16 December 1978. She was observed coiled upside down (ventrals up) on 14 January. She spent all of her time under a heat lamp in a nest box containing damp potting soil. The temperature at this location was 30 C day and 27 C night. She was frequently observed in the ventrals up position while in the box.

The female began to exhibit behavior that indicated she was ready for oviposition on 14 April, 1979 at 1000 h. The tail was in the center of her coils. She was contracting anterior to the vent. Her tail raised and she deposited the first egg at 1030 h. A total of 10 adherent eggs were deposited by 1445 h. The eggs measured from 36-48 mm ($\bar{x}$ = 39.9 mm) in length and weighed 13.7-17.7 g ($\bar{x}$ = 15.09 g). She had a post-ovipositional weight of 325.6 g.

Two eggs containing developing embryos discolored on 25 and 28 April for unknown reasons and subsequently failed to hatch or develop further. The first egg was slit on 1 June. Six hatchlings had emerged by 4 June. The two remaining eggs were opened on 5 June and contained dead, full term embryos. The live and dead specimens appeared normal in color, pattern and morphology in relation to other *L. childreni* observed by the author in other collections. Weight ranged from 7.3-9.5 g ($\bar{x}$ = 8.63 g) and total length ranged from 232-256 mm ($\bar{x}$ = 245 mm).

Ecdysis occurred on 12 and 13 June. All snakes accepted first meals of newborn mice by 21 June. Mean weight doubled by the 40th day after hatching from $\bar{x}$ = 8.63 to 18.35 g. The mean weight was 88.7 g at nine months of age.

DISCUSSION

Ross (1978) reported temperatures of 21.1-30.0 C in Australian and 25.0-29.4 C in North American collections during breeding periods. R. Cauble (pers. comm.) reported an annual temperature range of 26.7-29.4 C for his *L. childreni* in a breeding project. Results of this study were 20.0-26.7 C with a mean of 22.8 C for similar behavior patterns. The low temperatures previous to breeding are probably significant for the inducement of copulation. Previous to breeding activity the *L. childreni* were experiencing 30-18 C day/night fluctuations. This may have represented a winter period. Breeding then took place during the apparent spring (warming) cycle.

Copulation occurred in October (1 time), November (4), December (6), January (9) and February (5) in this study. Ross (1973) reported breeding from September through February and Ross (1978) reported breeding from April through August. R. Cauble (pers. comm.) reported no observed breeding activity although oviposition reflected a northern hemisphere fall breeding.

The unusual positioning of the female is characteristic of many pythons when gravid (personal observations). Ross (1973), Boos (in Ross 1973) and R. Cauble (pers. comm.) noted similar dorsal inversions of gravid *L. childreni*. The author has witnessed similar behavior in *Python molurus* ssp. at this facility. Conversely, a gravid *L. albertisii* exhibited no inversions here.

Ross (1973) reported 18 April and Ross (1978) reported February, March, April (3), May, June (2), October, November (2) and December as dates of oviposition. R. Cauble (pers. comm.) recently reported a clutch on 3 January, 1979.

Incubation time is somewhat variable in the literature. This report indicates 49-53 days ($\bar{x}$ = 52) at 31 C. Ross (1973) reported 66-67 days at 27.2-31.7 C and R. Cauble (pers. comm.) indicated 45 days at approximately 29.4 C. These variations are probably due to the differences in incubation temperature. In both reports the incubation temperatures were varied and the true average temperature was not readily ascertainable.

It appears that the breeding season of *L. childreni* is highly variable in captivity. It is probable that captive behavior is the result of cycling into existing conditions possibly unknown to the keeper. A preliminary hypothesis is set forth from this report; a mild winter period of lower night temperatures, followed by a comparatively stable warmer period, will result in mating behavior. These environmental conditions may be important in gonadal development and conditioning; leading to successful reproductive functions.

The controls have been repeated for the 1980 breeding season with similar results in relation to observed breeding at the date of this writing.

ACKNOWLEDGMENTS

I would like to thank Dan Chiras and Dale Marcellini for review of the original copy. I am also grateful to Tracy Miller for offspring growth data.

COURTSHIP AND COPULATORY BEHAVIOR OF CAPTIVE EASTERN HOGNOSE SNAKES, *Heterodon platyrhinos.*

Reproductive behavior of the eastern hognose snake, *Heterodon platyrhinos*, has been sparsely documented with details of oviposition, egg size and incubation, and hatching size. Edgren (1955) and Platt (1969) detailed the natural history, but did not discuss the courtship and copulatory behavior of these snakes. Reported here are observations of the courtship and copulatory behavior of a captive pair of *H. platyrhinos*.

METHODS AND MATERIALS

The male (550 mm SVL) was collected in Gloucester County, New Jersey on 30 July 1973. He was maintained in a 38 liter aquarium and was fed a diet of toads, frogs, and mice. The female (580 mm SVL) was taken on 26 April 1977 from the above locality and was maintained in the same aquarium with the male until 16 September 1978. She was removed to a cage (305 x 203 x 101 mm), after laying a clutch of ten eggs to prevent any further breeding. She was returned to the male's aquarium on 15 January 1979 for mating observations and removed after copulation occurred. She produced one clutch of fifteen eggs on 3 March 1979 and a second clutch of sixteen eggs on 4 September 1979.

OBSERVATIONS

The observations reported below occurred at various times during the fall of 1977. Although no copulation was observed during this period it probably occurred because the female produced a clutch of ten eggs ($\bar{x}$ = 6.7g; 35.5 x 18.1 mm) on 14 September 1978.

The male approached the female about three quarters of the way down her body and contacted her side with his rostrum. After contact, he advanced anteriorly along her laterally, nudging her with his rostrum as he moved. When he reached her neck, his body was parallel with that of the female. He continued to nudge her with his rostrum, looped his tail over hers and attempted to push a loop of his tail underneath. The undulations of the tail moved anteriorly until his entire body was undulating against the female's body. The female usually remained still but occasionally advanced. During most observations, the female moved away shortly before the male's tail search and copulatory attempt, but in one instance he was observed forcing his tail under hers, and the undulations of his body became more rapid causing the female to move quickly away.

The female laid a single yellow egg (4.2g; 37.9 x 15.6 mm) in the water dish on 14 September 1978 and the remaining nine eggs (4.0-8.7g; 27.8-40.5g x 14.8-20.1 mm) on 16 September 1978. The female was removed after egg laying and readily accepted food the following day. The eggs were opened on 15 December 1978 and found to be undeveloped.

On 15 January 1979, the female was returned to the male's aquarium for the below reported observation.

The male approached about three quarters of the way down the body of the female on the right side making tongue-flicks at a rate of about one per second. After contact with his rostrum, he moved anteriorly along the female's dorsum with his head pressed against her body. He made short tongue-flicks at a rate of about two - three per second and sudden jerking movements described as forward-jerking in rat snakes by Gillingham (1979). During his advance, the female occasionally moved forward with the male partially draped over her body. The male began to undulate his tail over the tail of the female and shortly thereafter these undulations moved anteriorly in waves described as caudocephalic waves in rat snakes by Gillingham (1979). He then forced a loop of his tail under the female's tail and began to rapidly move it back and forth.

Intromission was accomplished with the left hemipenis. The male was lying alongside the female with his head pressed against the back of her neck. The female periodically moved forward; the male's body moved apart from hers during coitus. Copulation lasted about five hours, after which the female was removed.

On 27 February 1979 she laid one yellow egg (5.7g; 33.0 x 18.6 mm), two white eggs (10.0, 8.3 g; 43.8 x 20.4 mm, 34.3 x 20.5 mm) were laid on 1 March 1979, and the remaining twelve eggs (4.0-9.2 g; 30.7-40.3 x 15.7-21.8 mm) were laid on 3 March 1979. The eggs began hatching on 13 May 1979 and averaged 75 days incubation (72-78 days) for seven eggs. Five other eggs failed to hatch but contained fully developed snakes. Hatchlings weighed 3.6-8.2 g (av. 5.3 g) and measured 126-157 nn SVL ($\bar{x}$ = 143 mm). After shedding the natal skin, the hatchlings were offered dead *Hyla crucifer*.

On 4 September 1979, without having been in contact with the male since 15 January 1979 the female laid 16 eggs (3.5-10.1g; 25.2-44.5 x 16.4-24.Omm). Eight eggs were discarded on 20 September 1979, four eggs hatched on 4 November 1979, two eggs were discarded on 10 November 1979, and the remaining two eggs were opened on 21 November 1979 and found to contain deformed snakes; one of them was dorsally bifurcated.

DISCUSSION

The courtship behavior of *H. platyrhinos* resembles the courtship of rat snakes as described in Gillingham (1979). The courtship can be broken down into several phases: 1) dorsal advance movement, 2) tail searching and copulatory attempt, and 3) coitis. The male did not chase the female, possibly because of the small confines of the cage or the female's receptiveness to the male. The male did not bite the female during copulation as in many other colubrid snakes but positioned his head along the dorsal surface of the female just behind the head.

There were differences between the first group of observations and the single observation. During the dorsal advance of the first set

Burbank, California 91505

of observations the male advanced along the side of the female, nudging her with his rostrum, possibly to stimulate reproductive behavior from the female. He did not exhibit forward jerking, which was noted in the later sequence. The male's approach during the early observations and his failure to elicit reproductive behavior from the female, may have been due to the female's sexual immaturity, small size, or age. Platt (1969) found that the western hognose, *H. nasicus*, with SVL of less than 360mm were immature and that of those 360-400mm SVL, seventy-five percent were immature. Since *H. platyrhinos* averaged slightly larger than *H. nasicus* (Platt 1969), it is believed that the female may not have given off the proper chemical stimuli to elicit proper courtship behavior from the male.

ACKNOWLEDGMENTS

I am grateful to John D. Groves for his help in the preparation of the manuscript. I thank my wife, Nancy, for her care and understanding during the study.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1978. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

ANURA

RANA CATESBEIANA (Bullfrog). **FOOD.** A bullfrog *(Rana catesbeiana)* was gigged by a frog hunter at approximately 10:30 p.m. on 11 July 1978 on the north bank of the Mississinewa River at the northwest corner of Botany Glen in Grant County, Indiana. Botany Glen is a natural area owned by Marion College and is described in Lindsey *et al.* (1969. Natural Areas in Indiana and Their Preservation. Purdue Univ., Lafayette, Ind. 594 p.)

The wing of a bat was observed protruding from the mouth of the bullfrog. The bat was dead but had apparently been ingested very recently. It was an adult female Big Brown Bat *(Eptesicus fuscus)* bearing band number BAT9-77182. It was banded as an adult on 5 August 1972 in a nursery colony of Big Brown Bats located in the attic of a two-story brick home in Gas City 2.3 mi (3.7 km) NW of Botany Glen. It was recaptured in the same colony on 11 September 1973.

The ingestion of bats by bullfrogs may be uncommon since a search of the literature revealed but two reports. Lee (1969. Notes on the Feeding behavior of cave-dwelling bullfrogs. Herpetologica 25:211-212) found the Southeastern Myotis *(Myotis austroriparius)* in the diet of bullfrogs in an Alabama cave. Korschgen and Baskett (1963. Foods of impoundment and stream-dwelling bullfrogs in Missouri. Herpetologica 19:89-99) found two Red Bats *(Lasiurus borealis)* in the stomachs of bullfrogs collected at a Missouri impoundment.

SERPENTES

AGKISTRODON CONTORTRIX PICTIGASTER (Trans-Pecos Copperhead). **NEONATES.** USA. Texas, Presidio County. Numerous accounts of the offspring of *A. contortrix* have been given in the literature (see Fitch, H. 1960. Univ. Kansas Mus. Nat. Hist. Publ. 13(4):85-288.); however, none has appeared for the subspecies *A. c. pictigaster.* On 16 August 1980, a brood of four (3 ♂, 1 ♀) offspring resulting from a captive mating was produced. Within 24 h after parturition, lengths and masses were obtained to the nearest millimeter and 0.1 g, respectively. S-V lengths: 200-210 mm ($\bar{x}$=205 ±4.08 mm); tail lengths: 41-47 mm ($\bar{x}$=44.5 ±2.52 mm); masses: 13.7-14.1 g ($\bar{x}$=13.9 ±0.03 g). Ecdysis occurred 9 days after parturition for all specimens, and subsequently color notes were taken. The neonates differ in coloration from the holotype (Gloyd, H. K. and R. Conant. 1943. Bull. Chicago Acad. Sci. 7(2):147-170.) in the following: (1) the dorsal crossbands are dark brown stippled lightly with tan; (2) the dorsal ground color is dark tan; (3) the venters are uniformly darker; (4) dark brown spots (usually paired) occur laterally on the dorsal crossbands principally in the caudal two-thirds of the body; and (5) the distal one-half of the tails are dull white (one dull yellow).

Submitted by **GORDON W. SCHUETT** and **FRED KRAUS,** Department of Biology, University of Toledo, Toledo, Ohio 43606, and Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109. ●

CROTALUS VIRIDIS CONCOLOR (Midget Faded Rattlesnake). **COLORATION.** USA. Wyoming, Sweetwater County. On 5 May 1979, James L. Glenn secured a specimen having extensive fusion of the dorsal blotches (only 6 anterior dorsal blotches are complete). There is no fusion of the tail blotches. Another Sweetwater *concolor,* captive born on 20 August 1979 to a wild-bred female (normal pattern) collected 5 May 1979, has some fused posterior dorsal blotches. On 25 September 1979, GWS secured from the same locality two additional *concolor* (A and B) with some fused dorsal blotches. Crotalines with fused dorsal blotches have been previously reported (Gloyd, H. K. 1958. Bull. Chicago Acad. Sci. 10(2); Nickerson, M. A. and C. E. Mays. 1973. Wasmann J Biol. 26(1):125-131.) but the occurrence of four aberrant *concolor* within an area of *ca.* 100 m^2 is unusual. Specimen A: a male (Fig. 1); total length of 414 mm; S-V length of 380 mm; dorsal color is tan with flecks of dark brown and gray; dorsal blotches are dark tan and well-defined, bordered by dark brown and outlined by white. A series of dorsolateral and lateral blotches are tan and dark brown, respectively. Five dorsal areas exhibit fused blotches; the greatest amount of fusion is directly behind the head (the first blotch is not fused) and extends posteriorly 55 mm. At mid-body there are two separate fusions (45 mm and 15 mm in length), and posteriorly two more (50 mm and 25 mm in length). Some

Fig. 1. Male *C. v. concolor.*

Fig. 2. Female *C. v. concolor.*

dorsolateral and some lateral blotches are fused. There is no fusion of the tail blotches. The venter is cream with dark brown concentrated along the lateral edges. Specimen B: a female (Fig. 2); total length of 499 mm; S-V length of 471 mm. This specimen is similar to the male except that: (1) fusion of the dorsal blotches occurs largely in one region with the largest amount located 80 mm behind the head (*ca.* 55 mm in length); at mid-body there is a two-blotch fusion, and (2) there is no fusion of the dorsolateral or lateral blotches. The scale counts of both specimens are typical for the subspecies. Gloyd (*op. cit.*) noted typical scale counts in crotalines he examined that had fused dorsal blotches. The specimens are being kept alive to determine whether they will produce offspring with pattern aberrations; however, similar aberrations in other snake taxa are known to result from suboptimal temperatures during embryogenesis (see Vinegar, A. 1974. Herpetologica 30:72-74 and references therein). We wish to thank L. Porras, L. D. Wilson, and J. L Glenn for their helpful comments on the manuscript. L. Porras kindly supplied one of the specimens.

Submitted by **GORDON W. SCHUETT** and **FRED KRAUS,** Department of Biology, University of Toledo, Toledo, Ohio 43606, and Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109. ●

EPICRATES SUBFLAVUS (Jamaican Boa). **FOOD.** A 2.0 m, 3.6 kg female(?) Jamaican boa was captured by W. Robinson on 24 July 1980 at White Horses, St. Thomas Parish, Jamaica, and taken to Hope Zoo, where it is now on exhibit. Four fecal samples contained the remains of a large mongoose, *Herpestes auropunctatus,* an adult rat, *Rattus cf. rattus,* boa teeth, and finely masticated pieces of beetles, ants, and grass. The insects and grass probably had been eaten by the mammals. It is possible that the mammals were taken as carrion, and it is possible that the rat was eaten by the mongoose, which was in turn eaten by the boa. The introduced mongoose has ravaged Jamaica's herpetofauna in general and *Epicrates subflavus* in particular. We are pleased to report that the tables may sometimes be turned.

Submitted by **JAMES R. BAIN,** Florida State Museum, Gainesville, Florida 32611 (present address: 1004 Hazel Way, Flagstaff, Arizona 86001) and **LARRY HURST,** Hope Zoo, Royal Botanical Gardens, Kingston 6, Jamaica (present address: U.S. Peace Corps, 9 Musgrave Avenue, Kingston 10, Jamaica). ●

LAMPROPELTIS GETULUS HOLBROOKI (Speckled Kingsnake). **FOOD.** On 11 February 1978 I introduced a 96 cm (S-T) speckled kingsnake *(L. g. holbrooki)* into a cage with a breeding pair of *L. g. yumensis,* each measuring about 137 cm (S-T). The three snakes were compatible, so were left together.

From 4 April through 27 April 1978, copulatory behavior between male and female *L. g. yumensis* was observed. Since the smaller *L. g. holbrooki* was not disrupting reproductive behavior between the other two snakes, it was left in the same cage.

On 11 June 1978, I discovered four eggs in the kingsnake cage. Since previous clutches from the female *L. g. yumensis* numbered 9, 16, 9, and 15 eggs, I thought it strange that only four eggs were laid this year. Later in the day when I removed the kingsnakes, I noticed great distention of the belly of the *L. g. holbrooki.* The shape of five engulfed eggs was easily detected on the ventral surface of this snake.

While Conant (1975. A field guide to reptiles and amphibians, Houghton Mifflin Co., Boston) mentions that kingsnakes eat turtle eggs, Porter (1972. Herpetology, W. B. Saunders Co., Philadelphia), Schmidt and Inger (1957. Living reptiles of the world. Doubleday and Co., Garden City), and others say nothing about kingsnakes eating snake eggs. During the three years the *L. g. yumensis* were kept together, they never ate eggs from any of their clutches.

Submitted by **ROBERT E. LEWKE,** Allied Health Division, District One Technical Institute, 620 W. Clairemont Avenue, Eau Claire, WI 54701. ●

LAMPROPELTIS TRIANGULUM (Milk Snake). **COLORATION.** Leucistic, aberrant eastern milk snake, *Lampropeltis triangulum triangulum* caught by Mark Lucas in August, 1980. This snake was found on the grounds of the Soldiers Home Hospital beside the Wabash River, located about three miles east of

Lafayette, Indiana. Because of the extreme pattern anomaly there was some question as to the identity of this snake but it feeds readily on pink mice, is a powerful constrictor and keys to an eastern milk snake. This area is about 50 miles north of the ranges of both *Lampropeltis t. syspila* and *L. calligaster.* The snake is being maintained in the collection of Ernie Wagner.

Submitted by **ERNIE WAGNER,** Curator of Reptiles, Woodland Park Zoo, Seattle, Wash. ●

TANTILLA RUBRA CUCULLATA (Blackhood Snake). **SIZE.** On 11 June 1980 an exceptionally large *Tantilla rubra cucullata* was found DOR by Lorna Trumbower on State Hwy. 118 near the intersection of Park Road 3, Jeff Davis Co., Texas. The specimen (UF 50785) is a male with a total length of 654 mm (502 mm SVL, 152 mm TL).

The record lengths for *T. r. cucullata* and *T. r. diabola* were reported by Conant (1975. A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co., Boston) as 438 mm and 552 mm, respectively. However, *T. r. diabola* was later synonymized with *T. r. cucullata* by Degenhardt, Brown, and Easterla (1976. The taxonomic status of *Tantilla cucullata* and *Tantilla diabola.* Texas J. Sci., 27(1):225-234). The specimen reported herein surpasses the reported record length for *T. r. cucullata* (=*diabola*) by 102 mm. This also represents a new record length for the species (L. D. Wilson, pers. comm.).

There are only three species of *Tantilla* which have been reported to approach or barely exceed 600 mm in total length. *Tantilla annulata* was reported to measure 590 mm by Dunn and Bailey (1939. Snakes from the uplands of the Canal Zone and of Darien. Bull. Mus. Comp. Zool., 86(1):1-22). *Tantilla moesta* is reported to measure 592 mm by Wilson (In press. A review of the colubrid snakes of the genus *Tantilla* of Central America. Milwaukee Public Mus. Contr. Biol. Geol.). *Tantilla semicincta* has been reported to measure 600 mm by Wilson (1976. Variation in the South American colubrid snake *Tantilla* (Duméril, Bibron, and Duméril) with

comments on pattern dimorphism) although a specimen with an incomplete tail would probably have exceeded this length. Therefore, the record length for the genus *Tantilla* is now held by the *T. r. cucullata* herein reported.

SAURIA

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). **CANNIBALISM.** Cannibalism in captivity has been reported in members of several families of lizards including Iguanidae, Scincidae, and Varanidae. This paper is the first report of cannibalism in a teiid species.

On April 20, 1979, an adult male *Cnemidophorus sexlineatus* weighing 9.6 g was captured in Chambers County, Alabama. The lizard was individually bagged and returned to the laboratory. Subsequent dissection of its digestive tract revealed an intact juvenile racerunner in its stomach. The juvenile, probably a hatchling from the previous summer, measured 27 mm SVL. The juvenile had been swallowed head first and showed little evidence of digestion, indicating it had been consumed just prior to the adult's capture.

Fox (1975, Cannibalism in natural populations. Ann. Rev. Ecol. System., 6:87-106) reported that cannibalism is not an aberrant behavior limited to a few taxa; rather, he suggested that is is normal behavior in healthy populations of fish, anurans, birds, mammals, and numerous invertebrates. He indicated that cannibalism might serve to eliminate competition before resources become limited. Furthermore, Fox suggested that population density as well as availability of alternative food may influence the intensity of this behavior. This was the only lizard which positively exhibited cannibalism of the 338 racerunners we collected in a study on hibernation. This male was collected during early spring soon after emergence from hibernation. During this time insect prey items are relatively scarce, a situation which may intensify cannibalistic behavior.

TESTUDINES

CHRYSEMYS PICTA (Painted Turtle). **COLORATION.** An unusual color morph of this species, tentatively designated "erythroxanthic," was collected in Livingston County, Michigan, in August 1980. The carapace has a symmetrical pattern of orange whorls outlined in black, on an olive-green background, with an orange, black-bordered, dorso-medial stripe. Head and soft parts are pale yellow. Legs and feet have a single dark lateral stripe, while the top of the head has a gray and olive figure bordered in black. The area between eye and nostrils has finer black streaking. Eye is white with a black pupil, and lacks the transverse stripe of normal specimens. Plastron is immaculate pale yellow. (See photo).

Ewert (1979. The embryo and its egg: development and natural history. In: Turtles: Perspectives and Research. Harless and Morlock, eds. Wiley and Sons, Inc., NY. 695 pp.) discusses variations in turtle pigmentation. The suggested causes include environmental extremes during egg incubation, and genetic factors. Aside from pigmentation, the present specimen is morphologically normal. It is presently being maintained alive at Cranbrook Institute of Science, Bloomfield Hills, MI, and will be deposited there upon death.

BOOK REVIEWS

ROCK LIZARDS OF THE CAUCASUS, by I. S. Darevskii. v, 276 pages, soft covers. Publ. by Indian National Scientific Documentation Centre, New Delhi, "1978" (first copies received in US April 1979). Available from US Department of Commerce, National Technical Information Service, Springfield, Virginia 22161 (Publ. TT 70-53086). Price $11.00.

In 1967 Ulya Darevsky published his important review of the rock lizards (genus *Lacerta*, subgenus *Archeolacerta*) of the Caucasus, the Crimea, Turkey and northern Iran. This monograph ("Skal'naye Yashcheritsa Kavkaza," Izdatel'stvo 'Nauka,' Leningrad, 214 pages plus errata, color plates I-II, photos 1-35) covers the systematics, geographic variation, ecology and phylogeny of the eight species in this group, including both bisexual and parthenogenetic forms. Darevsky's book is of broad interest to ecologists and evolutionary biologists because he deals at length with the problems of species criteria and taxonomic rank of parthenogenetic populations, the significance of hybridization between bisexual and parthenogenetic forms and the evolution of parthenogenesis. Herpetologists are especially interested in these issues because of the existence of all-female species of lizards (representatives in at least six families), salamanders *(Ambystoma)* and, apparently, some primitive snakes *(Typhlops)*. But for those who do not read Russian, the only other recent review had been that published by Darevsky in 1966 in the *Journal of The Ohio Herpetological Society*.

The need for a more comprehensive review in English has not been met through this translation of Darevsky's book by the Scientific Documentation Centre. Insofar as I have been able to check, the translation has been done accurately and the English version has also benefited from the scientific editorship of George Zug. The manufacture of the book, however, is poor. Several signatures of pages have already fallen out of my copy. There are numerous typographic errors and many crude attempts to correct others. The photos have been reproduced very badly; the line drawings look as if they were reprinted from xerox copies and have lost much detail when compared to the original. Despite these defects,

Pythons & Boas

Authentic 9 X 11 reproductions of antique B&W illustrations of the Boidae, with emphasis on scalation and coloration patterns. Print no. 1, featuring the Ringed, Children's, Carpet, Green, Olive, Papuan, Di Albert's, Amethystine, and Reticulated Pythons, is now available for only $5.95 + $1.50 postage. Reptile Reproductions, 1210 Fairbanks Drive, Austin, TX 78752.

this translation provides for the first time in English a detailed review of the subject yet this is now badly out of date as Darevsky and his colleagues have made important new studies in the last 15 years that are not covered at all in this translation.

KRAIG ADLER
Cornell University

SOUTH AFRICAN FROGS by N. I. Passmore and V. C. Carruthers, 1979. Witwatersrand University Press, Johannesburg, xxiii + 270 pp., cloth bound including an LP record of calls. Available from Witwatersrand University Press, 1 Jan Smuts Avenue, Johannesburg 2001, South Africe for R22.00 plus R2.00 for postage and packing.

This book makes a magnificent addition to the older treatments of the South African herpetofauna contained in Rose (1962), Wager (1965) and Poynton (1964). **South African Frogs** is the result of a continuing and fruitful collaboration between Neville Passmore, of the Department of Zoology, University of Witwatersrand, and Vincent Carruthers, whose fine photography places this book very high on the list of illustrated guides to any animal group published to date.

The book is designed as a field guide to the adults of the 84 anuran species (in 23 genera) recognised to date in South Africa, although its large size (21.5cm x 27.5cm) and glossy finish would discourage me from using it under true "field" conditions. In common with other recently published field guides to frogs (for example Barker and Grigg, (1977), for Australia), the authors exclude several undescribed species and subspecies. At the risk of treading on some taxonomists' toes, I rather regret this. The useful life of the guide could be extended, and more rapid resolution of taxonomic and distributional problems achieved if such forms were included, and identified at least to genus and/or species group. Menzies (1975) **Handbook of Common New Guinea Frogs** does not flinch from presenting such unresolved taxonomic problems.

The first sections of the book deal generally with species and sub-species; frog sounds; mating; spawn; development and tadpoles; colour, temperature, water and the skin; feeding and a field key to the genera. Some of the content of these early sections departs refreshingly from the usual fare of other treatments.

For example, male advertisement calls are interpreted functionally as part of a co-adapted 'specific male recognition system' (SMRS). 'Isolating mechanisms', which traditionally serve to reduce mis-matings between species, are thus only an effect, rather than the raison d'être of the specificity of intraspecific signal-receiver systems. This re-interpretation of the concept of 'isolating mechanisms' will lead to useful new insights into such topics as speciation by reinforcement, coexistence in complex communities and the evolution of signalling systems.

In the section on frog sounds, the mechanisms of call production, functions of calls and interpretation of sonagrams are briefly but usefully treated. I am uncertain why the term "mating call" is adhered to, rather than Wells's (1977) more useful term "advertisement call", particularly as the authors acknowledge more functions than mate attraction alone.

Ecological consequences of species-specific call structure variation and calling site selection in mixed-species choruses are also discussed. The remaining early sections of the book treat other aspects of frog biology in a general, but useful way.

A highlight of the book is a photographic key to the genera. The excellent half tone photographs of the key make each choice absolutely clear, avoiding the usual problems of written keys, with which one often struggles in a conflict of interpretation. The photographs, in addition to clearly illustrating the key's choices, also give the user a rapid appreciation of the whole appearance of the animal to be keyed out, in visual contract to the possible alternatives. Key characters are also arrowed, in a similar fashion to the Peterson system, further reducing the possibility of ambiguity. Species determinations are achieved by comparison among the systematic accounts within each genus.

A map of localities cited follows the key, although the map does not contain the names of larger political divisions (*e.g.* Transvaal, Natal) which are frequently mentioned in the text.

The majority of the text (pp. 42-255) consists of systematic accounts, in which each species is defined. The systematic accounts are arranged by genus, and the individual species' treatments are preceded by a diagnosis of the genus, and short notes on sexual dimorphism, eggs, tadpoles and distribution.

The notes on eggs and tadpoles are generally insufficient for positive identification, even to genus. This is hardly a harsh criticism — even treatments of well-worked faunas, such as North America (Conant, 1975) do not often provide keys to eggs and larvae. A key to eggs and larvae, possibly only to genus, would strengthen this book in its (hopefully) future editions.

The species' accounts contain scientific and common names, with limited synonymy; a superb colour photograph (sometimes more than one), usually on a natural background, a distribution map, a sonagram of the male advertisement call, notes on habitat, a life-size half tone photograph and diagnostic half tone photographs of the ventral surface, foot, thigh and/or hand. Again, the Peterson system is used to indicate diagnostic features. One slightly annoying omission is the lack of higher taxonomic, for example, familial, classification. This would assist the user when comparing the composition of the South African anuran fauna with those elsewhere. The broad distributions of species occurring more widely than South Africa alone are generally not mentioned.

The systematic section is followed by an Appendix containing characters used to differentiate recognised subspecies, a glossary of technical terms, a selected bibliography and an adequate index. Accompanying the book is a recording of all available calls, narrated by Carruthers. The recordings are of excellent standard, and are presented in the same order as the species' appearance in the text, so that visual and aural comparison is simple.

I have very few negative comments. Typographical errors are few. I discovered only two: on page 233 "comparatively" is mis-spelt, and on page 267 the citation of van Dijk, *Zool. Afr.* **6:**119-132, is undated. Errors of fact are also rare. One which caught my eye (page 129) is the statement that the genus *Rana* does not occur in the Australian region. One species does occur on the northern tip of Cape York Peninsula (Cogger, 1979).

Considerable use is made of Afrikaans terms such as kloof, fynbos and vlei without sufficient definition, at least for non-South African users. There is also some loose use of comparative statements, such as "large eggs", rather than a more explicit, and useful, quotation of an ovum diameter.

The layout of the book is very attractive, and easy to read, but the text could have been considerably compressed. Compression of the text might have permitted the production of a smaller book, although a reduction in the quality of the photographs seems a likely consequence.

The only obvious omissions are brief sections on field observation and collection techniques (the book is intended for amateurs, as well as scientists), and a treatment of photographic methods. Information on this topic is readily available elsewhere, however.

Passmore and Carruthers's book is a fine contribution to the herpetological literature of the world, and sets exacting standards for the authors of future field guides. **South African Frogs** is certain to provide a great impetus to studies of the ecology, speciation and behaviour of this incompletely-known fauna.

RARE AND ENDANGERED BIOTA OF FLORIDA: VOLUME THREE: AMPHIBIANS AND REPTILES edited by Roy W. McDiarmid. 1978. University Presses of Florida, Gainesville. xxii + 79 pp, cloth bound. $5.50.

This text represents the third in a four volume series on the rare and endangered biota of Florida. Other volumes have covered mammals, birds, and fish, respectively. Sponsored jointly by the Florida Audubon Society and the Florida Defenders of the Environment, each volume is designed as a concise compendium of biological information on the status and distribution of the endangered or threatened members of each major verebrate group within Florida. Considering the greatly increased public awareness for the plight of endangered species, and the fact that so many of these forms are found in Florida, it is not surprising that this series has been initiated. What is surprising is that the sponsoring agencies have been able to enlist the aid of so many scientists, researchers, and state and local officials to produce this timely and valuable volume.

The volume on amphibians and reptiles begins with a relatively long introductory section, providing a list of the species considered, a detailed description of the major terrestrial and wetland habitats utilized by herps within the state, and a tabular listing of all 45 endangered or threatened forms, as they occur in each habitat and county in Florida. Following the introduction comes the main bulk of the text, a series of 1-2 p. individual species accounts, each prepared by a different author., Each account consists of a detailed morphological description, as well as notes on range, habitat, life history, special characteristics and a list of selected references. A finely detailed map, showing the species' range both within Florida, and in North America, is also provided. These accounts are clearly not intended to be a complete description of the species' biology; rather they provide a concise introduction to what is currently known concerning each species within Florida. The amount of information varies widely with the author, but all accounts are adequate for the purposes of this volume.

I found relatively little to criticize about this text. The only serious problem concerns the rationale behind some of the classifications used, which were not always clear to the reader. For example, it is difficult to understand why the eastern indigo snake *(Drymarchon corais couperi)* is classified here as a "species of special concern", considering that the Federal government only recently (1978) classified it as threatened, and that the author of the account (p. 69) states that "currently the indigo snake is considered threatened and legally protected by the state of Florida". There are similar questions about the classification of a few other species, most notably the American alligator *(Alligator mississippiensis)*. Although there may be a sound biological basis for these classifications, the reasons behind them should be made clearer to the reader, especially those not familiar with Florida's herpetofauna.

Considering the number of authors involved, inconsistencies and typographical errors were uncommon, and did not significantly detract from the text. A few are mentioned here for the sake of completeness. On pp. 7 and 61, the selected references are not in order. For the sake of taxonomic consistency, *Pseudobranchus striatus* (p. 17) should be placed under Order Urodela, as are the other salamanders in the text, rather than under Caudata. On p. 24, the legend for the map insert is partially illegible. Papers cited as "in preparation" should not be placed in the selected references, or given a date of publication, as they are on pp. 7 and 61. On p. 33, the title is missing from the reference Jackson and Jackson (1968).

Despite some minor difficulties, the state of Florida has produced a handsome and valuable reference text, which will be useful to anyone working with endangered or threatened amphibians and reptiles, or to anyone interested in the herpetofauna of Florida. Conservation officials from other states would be well-advised to use this entire series as a model for their own endangered species publications. Finally, the price of this text ($5.50) makes it a good buy in these days of inflated prices.

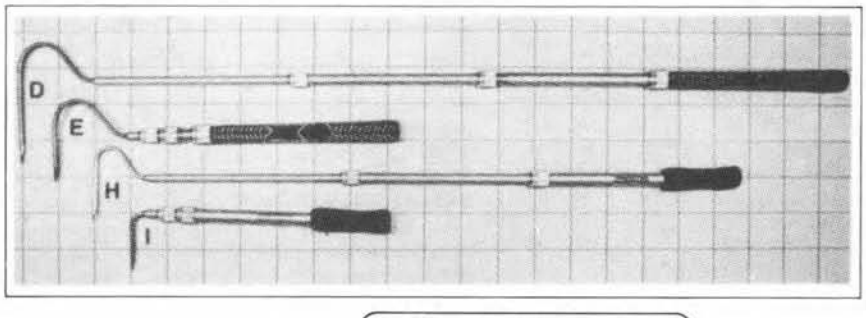
COLLAPSIBLE HANDLE HOOK

*Field & Cage Models



DESCRIPTION / PRICES:

A reliable locking mechanism has been acquired for our standard duty Field and Cage hooks. We are happy to offer it as an option in a 4 section configuration for models D or E, (length 19 - 46 inches) and for model G, (length 16 - 43 inches), rated to 10 pounds. **Price $32.50**

Cage hooks are available in a 3 section configuration for model H, (length 16 - 35 inches) and for model I, (length 14 - 33 inches). Cage hooks are available only with a short grip. **Price $23.50**

Write for our entire Reptile Equipment Catalog!

Texas residents add 5% sales tax. Thank You.

STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES (Second Edition)

By Joseph T. Collins, Roger Conant, James E. Huheey, James L. Knight, Eric M. Rundquist and Hobart M. Smith

Available in summer 1982. The first edition of this reference, issued in 1978 as SSAR **Herpetological Circular** No. 7, quickly became a standard reference for herpetologists, biologists, zoos, museums, conservation organizations, wildlife societies, book publishers, and Federal and state wildlife agencies. This second, revised edition is an up-date listing over 1300 common and scientific names for species and subspecies of North American (north of Mexico) salamanders, frogs and toads, crocodilians, turtles, lizards, and snakes. New features in this edition (not in the 1978 version) are an appendix of Hawaiian amphibians and reptiles, the inclusion of the names of describers for all genera, species and subspecies, and the addition of a table comparing the number of currently recognized subspecies with those listed in earlier publications. The SSAR Committee on Common and Scientific Names (shown above) considered over 50 proposed changes for this edition, the majority of which were adopted.

TO ORDER SSAR HERPETOLOGICAL CIRCULAR NO. 12* . . . . $3.00 Payment in U.S. funds only

SEND ORDERS TO:
DR. DOUGLAS H. TAYLOR, DEPARTMENT OF ZOOLOGY, MIAMI UNIVERSITY, OXFORD, OHIO 45056 USA. Make checks payable to "SSAR;" receipt on request. A pricelist of other Society publications can be obtained on request from Dr. Taylor, including the **Journal of Herpetology, Herpetological Review, Contributions to Herpetology,** other **Herpetological Circulars, Catalogue of American Amphibians and Reptiles,** and the **Facsimile Reprints in Herpetology** series.

***Herpetological Circulars are no longer distributed free to SSAR members; individuals desiring copies of this and future numbers should place their orders as per the above instructions.**

MELBOURNE HERPETOLOGICAL SYMPOSIUM PROCEEDINGS

This volume summarizing the 1980 symposium, is now available. The meeting, held at the Royal Melbourne Zoological Gardens, attracted 110 persons; 35 papers were presented. The volume's 199 pages are peculiarly broken into 9 macrodivisions which show more than a little overlap and hence are of questionable value. Hence, one finds a paper on farm management of *Chelonia mydas* under ***TURTLES AND TORTOISES*** rather than ***MANAGEMENT AND CONSERVATION,*** and several other inconsistencies. But, ignoring that, the volume is a fine treatise on the Australian herpetofauna as a whole and a valuable reference for anyone involved with captive propagation of reptiles. The additional papers on biogeography, physiology, taxonomy and natural history make this a well balanced volume suitable for use as a readings-in-herpetology text with an emphasis on Australia. For information on availability of the volume, write:

Chris Banks
The Royal Melbourne Zoological Gardens
P.O. Box 74 Parkville
Victoria 3052

NEWSNOTES

PSEUDACRIS TRISERIATA BREEDING DATES SOUGHT

I am gathering data for a summary of breeding dates of *Pseudacris triseriata* throughout its range, hoping to relate the mean and variance of breeding dates to climatic variables, and would very much appreciate copies of obscurely published data about breeding of this species or lists of observations of breeding, giving the locality, date, and evidence of breeding (amplecant pairs or eggs). Any data received will, of course, be fully acknowledged.

FREDERICK W. SCHUELER

SALAMANDRIDS NEEDED

Frederick J. Prohaska (9901 W. Hampton #4, Milwaukee, WI 53225, phone (414) 438-1774) would like to obtain specimens of *Triturus alpestris, T. cristatus, T. marmoratus, Paramesotriton deloustali* and *Salamandra salamandra* for hybridization experiments. He is willing to pay or trade for them if that would stimulate responses. ●

VENOMOUS ANIMAL SOCIETY FORMED

The Venomous Animal Society of Canada has recently formed and has subsequently released the first issue of their Journal (No. 1: June 1981).

The goal of the V.A.S.C. is "to provide a vehicle for the exchange of information and ideas to those members of the zoological community with an interest in venomous animals." Membership is open to persons with an interest in venomous animals in general, and is not restricted to reptiles and amphibians alone.

Membership fees are $10.00 Canadian/year and it is anticipated that three or four issues of the Journal will be published per year.

Interested persons may write to:

Scott Allen
11 Knightsbridge Road, #1010
Bramalea, Ontario
L6T 3X4 Canada ●

ANNUAL MEETING SITES

The SSAR and Herpetologists' League are considering annual meeting sites for 1984 and beyond. Sites are selected with attention to accessibility, facilities for meeting rooms and housing, and relatively low costs for housing and meals. Persons interested in hosting the SSAR/HL annual August meetings should contact Lynne Houck [Department of Biology, University of Chicago, 1103 East 57th Street, Chicago, IL 60637; (312) 753-2803] for more information. ●

ENDANGERED SPECIES DATA SOUGHT

Rom Whitaker, Chairman of the Species Survival Commission-Snake Group, is requesting up-to-date information on snake species for the Red Data Book of the International Union for the Conservation of Nature (I.U.C.N.). More specifically, Whitaker is requesting the following:

1) What snake species in your area do you consider endangered or under heavy pressure?
2) Suggested action/study (e.g., status survey, etc.).
3) Names and addresses of people who could contribute information and be involved with follow-up work.

For more information, write Romulus Whitaker, SSC Snake Group, Madras Snake Park, Madras 600 022, South India. ●

HR REVIEWERS

Thanks are expressed to the following persons who have reviewed articles for **HR:**

Peter Brazaitis	Edward Maruska
R. Bruce Bury	Robert Mount
Jonathan Campbell	N. Mrosovsky
John Frost	Martin J. Rosenberg
Carl Gans	John W. Wright

AMPHIBIAN SPECIES SURVIVAL PLAN

The American Association of Zoological Parks and Aquariums is assembling a list of Amphibians to be included in its species survival plan. Criteria that should be considered for species selection is the availability of specimens to insure good genetic make up for captive management and the need for conservation efforts based upon population status in the wild. Suggestions for species to be included on this list should be forwarded to: Frederick L. Paine, Curator of Birds and Reptiles, Buffalo Zoo, Delaware Park, Buffalo, NY, 14214. ●

FIRST INTERNATIONAL COLLOQUIUM ON PATHOLOGY OF REPTILES AND AMPHIBIANS

SEPT. 29 - OCT. 2, 1982 - ANGERS (FRANCE)

This Colloquium will be held at the University of ANGERS. Every aspect of pathology will be examined: microbial and viral infections, parasitism, tumors, malformations, physiopathologic diseases, hybrid lethality, etc. Sessions will start with synthethis reports; communications will be done in the form of brief statements. Table meetings could be organized in relation with the various aspects of pathology according to the different proposals.

This Colloquium is co-organized by:

C. VAGO
Membre de l'Institut
Professeur à l'Université des
Sciences et Techniques du Languedoc
Laboratoire de Pathologie comparée
Place Eugène Bataillon
34060 MONTPELLIER Cedex
France
and
G. MATZ
Professeur à l'Université d'Angers
Laboratoire de Biologie animale
2, Boulevard Lavoisier
49045 ANGERS Cedex
France ●

Pre-register via letter to G. Matz. The registration form, call for papers and program will be sent in March '82.

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

CAUDATA

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: VIRGINIA: Campbell Co: 15.7 km ENE Gladys. 14 April 1981. Lenny Jones. Verified by R. N. Bader and J. C. Mitchell. Nat. Mus. Nat. Hist. (USNM 221845). Charlotte Co: South Isle Plantation, 10.4 km SSW Phenix. 20 March 1981. Dale Belcher and Robert N. Bader. Verified by J. C. Mitchell. Collected as larva and metamorphosed in captivity. (USNM 221846). 10.4 km SSW Phenix. 18 April 1981. Joseph C. Mitchell and Robert N. Bader. (USNM 221847, larva). 10.4 km SSW Phenix, 21 April 1981. Robert N. Bader and Ben Greishaw. (USNM 221848, larvae). These records extend the range of this species northward in eastern North America and establish its presence in Virginia (Conant, R. 1975. A Field Guide to the Amphibians and Reptiles of Eastern North America, Houghton Mifflin Co., Boston; Martof, B. S., et al. 1980. Amphibians and Reptiles of the Carolinas and Virginia, Univ. North Carolina Press, Chapel Hill). These localities lie 155 km (Charlotte County) and 163 km (Campbell County) northeast of a single known population in southeastern Surry County, North Carolina (Alvin Braswell, pers. conn.).

Submitted by **ROBERT N. BADER,** Route 2, Box 78, Brookneal, Virginia 24528 and **JOSEPH C. MITCHELL,** Department of Biology, University of Richmond, Richmond, Virginia 23173. ●

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: VERMONT: Chittenden Co: Shelburne Pond, 8 km E Shelburne; 5 November 1968; University of Vermont Museum of Zoology (AM-5410) and Williston Bog, 1.8 km S Williston; 1 May 1960; University of Vermont Museum of Zoology (AM-5408). Verified by C. A. Woods. This report provides more precise locality information than is presently available for the range of *Hemidactylium* in Northern Vermont. These two localities are approximately 50 km north of the range indicated in Vermont by Neill (1963, Cat. American Amphib. Rept., 2:1-2).

Submitted by **C. WILLIAM KILPATRICK,** Department of Zoology, University of Ver-

mont, Burlington, Vermont 05405, and **CHARLES A. WOODS,** Department of Natural Sciences, Florida State Museum, Gainesville, Florida 32611. ●

ANURA

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog). USA: TEXAS: Young County: 8 km NE of Eliasville on FM 701 in Clear Fork of Brazo's River. 14 June 1981. C. T. McAllister. Verified by L. C. Fitzpatrick. North Texas State University Herpetological Collection (NTSUHC #A-43). First record for the county and virtually fills distributional hiatus of central and eastern Texas, except for adjacent Clay and Stephens counties (Raun and Gehlbach, 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2). Additional *A. c. blanchardi* were photographed and released along with smypatric *Rana blairi=Rana pipiens* complex (see Hillis, D. M. 1981, Copeia 1981:312-319) and *Rana catesbeiana.*

Submitted by **CHRIS T. MCALLISTER** and **MICHAEL C. WOOTEN,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

HYLA SMARAGDINA. Mexico: Jalisco: 21 km WSW Ameca, 20 July 1971, University of Texas at El Paso (UTEP 6971, adult); Jalisco, 10 km SW Autlan, 15 July 1966 (UTEP 8038-48, adults); Jalisco, 26 km SW Autlan, 20 July 1972 (UTEP 8053, larvae, N = 49); Mexico, 2-3 km S Nuevo Santo Tomas, 18 July 1968 (UTEP 8448, larva, N = 1); Nayarit, 16 km N Compostela, 13-14 July 1970 (UTEP 6990-92, adults); Nayarit, 15 km WSW Compostela, 14 July 1970 (UTEP 8035-36, adults); Puebla, 13 km SE Izucar de Matamoras, 19 July 1968 (UTEP 7758-63, adults; UTEP 7764, larvae, N = 22). All collected and identified by author. These localities provide additional records of occurrence in Nayarit, and are the first for the states of Jalisco, Mexico, and Puebla (Duellman, Hylid Frogs of Middle America, 1970: 414, fig. 210; 712).

Submitted by **ROBERT G. WEBB,** Laboratory for Environmental Biology, University of Texas at El Paso, El Paso, Texas 79968. ●

TESTUDINES

CARETTA CARETTA GIGAS (Pacific Loggerhead). USA: WASHINGTON: 17 February 1981. Fort Canby State Park, Ilwaco (Lat. 46.18 N., Long. 124.03 W.). Stranded on beach. Near death, body temperature 8-10 degrees C. Turtle transported to The Seattle Aquarium and placed under care of veterinarian. As aquarium water temperature gradually increased to 15 degrees C., the turtle began to swim. Health stabilized at The Seattle Aquarium (John Nightingale, Curator, pers. comm.). In cooperation with National Marine Fisheries Service specimen transferred to Sea World, San Diego, California to continue rehabilitation. Specimen tagged and released in open ocean off San Diego on 30 June 1981 (William Dickensen, NMFS, pers. comm.). This is the first *Caretta* record for the state of Washington, considerably north of "Southern California" (Stebbins, 1966, A Field Guide to Western Amphibians and Reptiles, Houghton-Mifflin Co., Boston.)

Submitted by **ROBERT PARKER HODGE,** 181 Raft Island, Gig Harbor, Washington 98335. ●

CHRYSEMYS CONCINNA (River Cooter). USA: TEXAS: Van Zandt Co: Fruitvale. Collected on Hwy 80. 4 April 1981. S. Myers and C. Whitfill. Verified by J. P. Karges. University of Texas at Arlington (UTACV-R-10322). This specimen appears to be an intergrade between the subspecies *texana* and *hieroglyphica. C. concinna* and *C. floridana* have been used interchangeably in the literature. Many East Texas populations are three-way intergrades among the ssp. *texana, hoyi,* and *mobilensis* (A. F. Carr, pers. comm.). This record helps fill the gap in the North Sabine River drainage hiatus (Raun and Gehlbach, 1972, Dallas Mus. Nat. Hist. Bull., 2:1-61).

Submitted by **STEVEN MYERS,** 4115 Douglas Ave., Dallas, Texas 75219. ●

CLEMMYS INSCULPTA (Wood Turtle). USA: NEW YORK: Suffolk Co: Islip, crossing Southern State Parkway, 2 km west of Islip exit. 5 July 1981. Identified by Robert Price. A single adult male was observed. No specimen was taken due to endangered and protected status. Neither Conant (1975, A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co.) nor Ernst and Barbour (1972, Turtles of the United States, Univ. Press of Kentucky) include Long Island in the range of this species. *Clemmys insculpta* is known to occur some 55 km to the north (across Long Island Sound) in Connecticut, and some 100 km to the west in suburbs of New York City. Although the western part of Long Island (Kings, Queens, and Nassau counties) contains little woodland habitat suitable for this species, it is reasonable to assume relict populations existing in undeveloped areas of eastern Long Island.

Submitted by **ROBERT PRICE,** 1450 Blue Spruce Lane, Wantagh, New York, 11793. ●

GRAPTEMYS PULCHRA (Alabama Map Turtle). USA: Georgia: Whitfield County: Conasauga River (Coosa drainage) at Mitchell Bridge, 10.9 km ENE Dalton. 12 November 1978. J. L. Harris. Verified by C. J. McCoy. One juvenile (sex undetermined) taken from river. Skeleton only (UGAMNH 15018). First record for state and extends range approximately 110 km east of previously recorded locality (Mount, 1975. The reptiles and amphibians of Alabama. Auburn Printing Co., Auburn).

Submitted by **JOHN L. HARRIS,** Arkansas Department of Highways and Transportation, P.O. Box 2261, Little Rock, Arkansas 72205; **JOSHUA LAERM** and **LAURIE J. VITT,** Museum of Natural History, University of Georgia, Athens, Georgia, 30602. ●

STERNOTHERUS ODORATUS (Stinkpot). USA: NEW YORK: Jefferson Co: Millsite Lake, Town of Theresa. 6 June 1981. R. J. Gawlik. American Museum of Natural History (AMNH 120618). Verified by M. W. Klemens. Additional specimens were captured at Millsite Lake on 27 June 1981 (1) and 12 August 1981 (2) and later released at the lake unharmed. A specimen collected at Millsite Lake on 11 July 1970 (collector unknown) is stored in the collection of the Rice Creek Biological Field Station of the State University of New York at Oswego (RCBFS 60). This report extends the species' northern New York range approximately 10 km to the SE of its reported occurrence at Goose Bay Marsh on the St. Lawrence River (Petokas and Alexander, 1979, SSAR Herp. Review 10(4):118). Millsite Lake is one of a series of lakes (the Indian River Lakes) that empty into the St. Lawrence River along the same drainage and we speculate that the stinkpot will eventually be found to inhabit all of those lakes.

Submitted by **PETER J. PETOKAS,** Department of Biological Sciences, State University of New York, Binghamton, New York 13901 and **RANDY J. GAWLIK,** Department of Biological Sciences, State University of New York, Cortland, New York 13045. ●

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). USA: MASSACHUSETTS: Dukes Co: Naushon Island, 12.9 km SW of Woods Hole, Barnstable County. Adult male found 14 July 1981 by Joseph A. DePari and John Kemp. Verified by Terry E. Graham of Worcester State College. Harvard University, Museum of Comparative Zoology, Herpetology Slide Collection 772-777. First verified specimen from the Elizabeth Island chain, town of Gosnold, filling a gap in the range between the Massachusetts mainland to the north and the island of Martha's Vineyard to the south. The author also observed a nesting female *Terrapene carolina carolina* on Naushon Island on 15 June 1980 which was not collected or photographed. (Lazell, 1976, This Broken Archipelago, Cape Cod and the Islands, Amphibians and Reptiles, Publ. Quadrangle/The New York Times Book Co., 262 pp.)

Submitted by **JOSEPH A. DEPARI,** Worcester State College, Department of Biology, 486 Chandler Street, Worcester, Massachusetts 01602. ●

TERREPENE CAROLINA CAROLINA (Eastern Box Turtle). USA: PENNSYLVANIA: Indiana Co: 1.6 km NW of Smithport. 5 September 1981. Jeffrey E. Lovich. George Mason University (GMU 756). This locaiity record extends the distribution some 80 km north of that suggested for west-central Pennsylvania (Adler, 1969. The influence of prehistoric man on the distribution of the box turtle. Annals of Carnegie Museum, 41(9):263-280). Another specimen has been collected in the county at the Indiana University of Pennsylvania Cooperative Farm (Dr. Arthur Hulse, person. comm.).

Submitted by **JEFFREY E. LOVICH,** George Mason University, 4400 University Drive, Fairfax, Virginia 22030 ●

SAURIA

CNEMIDOPHORUS SEXLINEATUS SEXLINEATUS (Six-lined Racerunner). USA: MARYLAND: Allegany Co: 8.2 km E of Oldtown, along Chesapeake & Ohio Canal. September 19, 1980. E. L. Thompson and J. Griffith. Verified by E. L. Thompson. Appalachian Environmental Laboratory (AEL-90). In Maryland, predominantly a coastal plain species which has extended its range westward through the piedmont and onto the valley and ridge via the Potomac River valley. This record represents a westward extension of 5 km from a previous Allegany County locality (Harris, 1975. Bulletin Maryland Herpetological Society. 11(3)). At this time, a substantial distributional gap exists along the Potomac River valley between Allegany County populations and coastal plain populations.

Submitted by **EDWARD L. THOMPSON,** Maryland Wildlife Administration, Route 2, Box 520, Frostburg, Maryland 21532. ●

HEMIDACTYLUS GARNOTI (Indo-Pacific gecko). USA: FLORIDA: Monroe Co: Dry Tortugas: Garden Key: 16 September 1981. Todd M. Steiner. Verified by Peter Meylan, Florida State Museum. (FSM 51-255). This is the first record for this species from the Dry Tortugas. Collected under permit from National Park Service, Everglades National Park.

Submitted by **TODD M. STEINER** and **LYNETTE T. McLAMB,** South Florida Research Center, Everglades National Park, P.O. Box 279, Homestead, Florida 33030. ●

SERPENTES

CROTALUS BASILISCUS OAXACUS (Oaxacan Rattlesnake). MEXICO: OAXACA: northern outskirts of Tlaxiaco, LOR, about 1971. Native collector, presented by Alan Downs. Head and anterior neck only. Identified by H. M. Smith. Head width 36 mm, depth 22 mm. Has four scales in the internasal-prefrontal area, part of the anterior median dark blotch, and no longitudinal dark lines on head or neck, all distinguishing the specimen from *C. durissus culminatus*, the only other large rattlesnake occurring in the area (Klauber, 1972, Rattlesnakes, 1:32-35, 132, figs. 2:2, 2:4, 2:14, 2:20). Univ. Colorado Mus. 54088. About 75 air km west of nearest other records (Armstrong and Murphy, 1979, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 5:8) for El Tejocote, Rio Colorado near El Tecote, and 35.5 km NW (San Francisco) Telixtlahuaca. Only other records in Oaxaca are for the types (Gloyd, 1948, Nat. Hist. Misc. 17:1-4), from Oaxaca (city) and (San Pablo) Yaganiza, east of Armstrong and Murphy's localities. The Tlaxiaco record is of special interest in documenting occurrence of the subspecies westward from central Oaxaca in the Sierra Madre del Sur, lending credibility to the generally neglected record, originally by Hoge in 1966 (Mems. Inst. Butantan, 32 [for 1965]: 136) for the "Chilpancingo region," Guerrero. Hoge and Romano (1971, Bücherl and Buckley, Venomous animals, 2:261, fig. 6) reiterated the Guerrero citation, but failed to map it. No other synopsis has noted the purported occurrence of the subspecies in Guerrero, except for Smith and Smith (1976, Synopsis Herpetofauna Mexico, 3:S-F-17). Presumably the subspecies ranges throughout the Sierra Madre del Sur in suitable habitats, as many other taxa do (e.g., *Sceloporus mucronatus omiltemanus*), and is not limited to central Oaxaca as frequently assumed. Certainly *C. b. oaxacus* ranges at least into western Oaxaca. Extension of its range in Guerrero requires confirmation since *C. d. culminatus* is the large rattlesnake recorded for the Chilpancingo region (Klauber, 1952, Bull. Zool. Soc. San Diego, 26:67). However, habitats preferred by both species do exist in that region (as well as in Oaxaca), and it would not be expected that Hoge could confuse two species so markedly distinct.

Submitted by **JOHN C. SPENGLER** and **HOBART M. SMITH,** Department of E.P.O. Biology; **DAVID CHISZAR,** Department of Psychology, University of Colorado, Boulder, Colorado, 80309; and **GUSTAVO CASAS-ANDREU,** Instituto de Biología, UNAM, Apdo. Postal 70-153, México, D.F. 04510, México. ●

ELAPHE GUTTATA GUTTATA (Corn Snake). USA: MARYLAND: Allegany Co: 8.3 km E of Oldtown, along Chesapeake & Ohio Canal. May 25, 1981. E. L. Thompson and J. Dimpsey. Verified by E. L. Thompson. Appalachian Environmental Laboratory (AEL-91). This record represents a westward range extension of 20 km in Allegany County. The corn snake is more commonly found on Maryland's coastal plain. Populations located in Allegany County, which lies within the valley and ridge physiographic province, appear to be isolated from coastal plain populations (Harris, 1975. Bulletin Maryland Herpetological Society. 11(3)).

Submitted by **EDWARD L. THOMPSON,** Maryland Wildlife Administration, Route 2, Box 520, Frostburg, Maryland 21532. ●

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). USA: VERMONT: Addison Co: 6.5 km S Monkton. June 1978. Gordon R. Nielsen. Verified by C. William Kilpatrick. Museum of Zoology, University of Vermont No. 6411. First record for county and fills in gap in poorly known portion of the range between southeastern Ontario (Pope, 1946. *Snakes of the Northeastern United States.* N. Y. Zool. Soc.) and Frankland County, Massachusetts (Lazell, 1979. Herp. Review 10:60). Extends range approximately 35 km N to new northern limit in state (Conant, 1974. *A Field Guide to Reptiles and Amphibians of Eastern and Central North America*, Houghton-Mifflin Co., Boston).

Submitted by **C. WILLIAM KILPATRICK,** Department of Zoology, University of Vermont, Burlington, Vermont 05405, and **MICHAEL A. ROMANO,** Department of Zoology, Miami University, Oxford, Ohio 45056 ●

MASTICOPHIS TAENIATUS (Striped Whipsnake). USA: ARIZONA: Yuma Co: Kofa Mountains, Kofa National Wildlife Refuge, Kofa Queen Canyon, 650-900 m. 4 April 1978 and 31 May 1981. R. P. Reynolds and M. A. Williamson, respectively. Two adults taken. Verified by M. A. Williamson and N. J. Scott, Jr. Deposited in United States National Museum (USNM 221844, 221843). Individuals taken in dry rocky, desert canyon. Commonest plant associates in order from greatest cover to least: *Simmondsia chinensis, Cercidium microphyllum, Larrea tridentata, Encelia farinosa,* and *Acacia greggi*. Vegetative cover about 25% in the wash community. Extends range approximately 190 km SW of Horsethief, Yavapai County (Fowlie, 1965, The Snakes of Arizona, Azul Quinta Press, Fallbrook, California). These are the first records of this species in Arizona south of the central plateau and the locality approaches the northwestern limit of the similar *M. bilineatus* in the Ajo Mountains, 200 km SE.

Submitted by **MICHAEL A. WILLIAMSON,** 7401 Central NE, Albuquerque, New Mexico 87108 and **NORMAN J. SCOTT, JR.,** Denver Wildlife Research Center, U.S. Fish and Wildlife Service, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131. ●

TROPIDOCLONION LINEATUM (Lined Snake). USA: NEW MEXICO: Bernalillo Co: 6.5 km ESE Sandia Park, T11NR6E Sec. 28, 2200 m. 13 June 1981. Veronica and Carmen Williamson. One juvenile. Deposited in United States National Museum (USNM 221842). Juniper grassland. Verified by M. A. Williamson and N. J. Scott, Jr. This locality extends the range of the northeastern New Mexican populations 85 km SW (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston) and decreases the gap between these populations and the isolated populations in the Capitan Mountains 200 km to the southeast.

Submitted by **MICHAEL A. WILLIAMSON,** 7401 Central NE, Albuquerque, New Mexico 87108 and **NORMAN J. SCOTT, JR.,** Denver Wildlife Research Center, U.S. Fish and Wildlife Service, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131.

MUSEUM AND LITERATURE RECORDS FOR THE RAINBOW SNAKE *(FARANCIA ERYTROGRAMMA* PALISOT DE BEAUVOIS)

In analyses of herpetofaunal distributions, particularly at the state level, locality records are often referenced by county. Geographic range extensions frequently refer to the Catalogue of American Amphibians and Reptiles. However, one must usually obtain exact locality information from the author for accurate measurements of distances between localities. To help alleviate this problem for *Farancia erytrogramma* (Mitchell, in press), the following known county records are presented. Museum records are listed first and are followed by literature records.

Farancia erytrogramma erytrogramma (Rainbow Snake). USA: ALABAMA: Baldwin, Chilton, Covington, Escambia, Henry, Limestone, Mobile, Shelby and Tuscaloosa. FLORIDA: Alachua, Clay, Duval, Columbia, Escambia, Franklin, Jackson, Jefferson, Leon, Liberty, Marion, Pinellas, Putnam, St. John, Santa Rosa, Wakulla, Washington; Walton (Neill, 1958). GEORGIA: Bibb, Bleckly, Bryon, Burke, Chatam, Dougher, Emanuel, Glynn, Liberty, Long, McIntosh, Richmond, Wayne; Wilcox (Gordon, 1957). LOUISIANA: East Baton Rouge, St. Tammy, Washington. MISSISSIPPI: Clarke, Harrison, Hancock, Jackson, Copiah, Forest, Lowndes, Oktibbeha; Pearl River and Stone (Cliburn, 1959, 1965). NORTH CAROLINA: Beaufort, Brunswick, Carteret, Chowan, Craven, Currick, Cumberland, Columbus, Dare, Duplin, Hyde, Jones, Moore, Pitt, Tyrrell; Camden and Paskotank (Brothers, 1965), Lenoir (Yarrow, 1882), New Hanover (Myers, 1924). SOUTH CAROLINA: Aiken, Barnwell, Beaufort, Berkeley, Bamberg, Charleston, Chesterfield, Colleton, Dorchester, Georgetown, Hampton, Horry, Jasper, Lexington, Lee, Orangeburg, Sumpter; Richmond (Corrington, 1929; Sanders, 1966). VIRGINIA: James City, King and Queen, New Kent, Southampton, Virginia Beach, York, Hanover and Surry (F. J. Tobey, Jr., pers. comm).

Farancia erytrogramma seminola (South Florida Rainbow Snake). USA: FLORIDA: Glades.

ACKNOWLEDGMENTS

I thank the following people and their institutions for providing locality records and/or literature references: J. R. Bailey (Duke University), G. R. Brooks (College of William and Mary), S. Busack and R. Crombie (U.S. National Museum of Natural History), J. T. Collins (Museum of Natural History, University of Kansas), N. H. Douglas (Northeast Louisiana University), H. A. Dundee (Tulane University), B. J. Freeman (University of Georgia), P. G. Haneline (Museum of Comparative Zoology, Harvard University), T. Hardaway (University of Southwestern Louisiana), H. S. Harris (Natural History Society of Maryland), D. F. Hoffmeister (University of Illinois), A. G. Kluge (Museum of Zoology, University of Michigan), T. C. Lewis (Florida State University), D. W. Linzey (University of South Alabama), E. V. Malnate (Academy of Natural Sciences, Philadelphia), H. Marx (Field Museum of Natural History, Chicago), C. J. McCoy (Carnegie Museum, Pittsburgh), P. Meylan (Florida State Museum, University of Florida), R. H. Mount (Auburn University), C. A. Pague (personal communication), W. M. Palmer (North Carolina State Museum of Natural History), D. A. Rossman (Museum of Zoology, Louisiana State University), A. E. Sanders (Charleston Museum), O. W. Thornton (Texas A&M University), F. J. Tobey, Jr. (Virginia Herpetological Society), C. H. Wharton (Georgia State University), G. K. Williamson (Savannah Science Museum), D. C. Whitman (Cornell University), R. G. Zweifel (American Museum of Natural History).

A POPULATION OF *Tupinambis* FROM NORTHERN PATAGONIA, SOUTH OF THE RIO NEGRO, ARGENTINA

The geographical distribution of *Tupinambis rufescens* (Gunther) and taxonomic relationships between this southernmost tegu and *Tupinambis teguixin* (Linnaeus) are still in need of revision in their area of sympatry. According to Presch (1973), *T. rufescens* ranges from about 22° to 38° 40' South latitude in western and central Argentina where it is a characteristic Chacoan element, mostly in the arid, depauperate southern Chacoan province, the Creosote bush scrub or Monte. Although the Monte vegetation is distributed over extensive areas of north-eastern Patagonia in Rio Negro and Chubut provinces, *T. rufescens* has not been reported from south of the Río Colorado. In February 1980 a population of *T. rufescens* was discovered in the Gran Bajo del Gualicho depression, 60 km South of the Rio Negro at about 40° 30' S, 65° 30' W. Soil in the Gran Bajo del Gualicho reflects a typical salt desert environment, at elevations of ~10 120 m. A characteristic xerophytic Monte vegetation is dominated by *Larrea nitida, L. divaricata* and *L. cuneifolia, Condalia, Cercidium, Prosopis strombulifera, Chuquiraga erinacea* and *Atriplex.* Reptiles found in association with *Tupinambis* included *Liolaemus darwini,* snakes of the genera *Philodryas* and *Leimadophis,* and the tortoise, *Geochelone donosobarrosi.*

This southernmost Patagonian *Tupinambis* inhabits sandy soils, forages into scrub in midday, and takes shelter in ravines. Probably it is a distributional relic of a milder interglacial period. Its survival may have been dependent upon moderate Pleistocene climates in the Gran Bajo del Gualicho.

TEXAS AMPHIBIANS AND REPTILES: SOME NEW DISTRIBUTIONAL RECORDS, PART IV

INTRODUCTION

This fourth serial report of new Texas distributional records includes only snakes; each record is substantiated with specimens in the University of Texas at Arlington Collection of Vertebrates (UTACV). These records supplement the range maps presented in Raun and Gehlbach (1972). I have used the nomenclature of Collins, *et al.* (1978) except for following Frost and Van Devender (1979) on the status of *Sonora semiannulata*. The abbreviations "US", "TX.", and "FM" refer to highway designations for national highways, state highways, and farm- (or ranch-) to-market roads, respectively. I verified the identifications, and I thank W. F. Pyburn and J. L Darling for access to the UTACV.

SERPENTES

Leptotyphlops d. dulcis (Plains Blind Snake): SAN SABA Co. 4.7 km S, 1.6 km E Bend. 10 April 1976. J. L. Darling. UTACV-R-7890-7891. WILLIAMSON Co. Georgetown Country Club. 22 May 1969. H. W. Greene. UTACV-1599.

Coluber constrictor flaviventris (Eastern Yellowbelly Racer): BRAZORIA Co. Lake Jackson. 24 May 1963. R. D. Burkett. UTACV-R-2296.

Elaphe guttata emoryi (Great Plains Rat Snake): COLEMAN Co. 16 km SE Santa Anna on FM 1176. 31 August 1974. G. G. Riddle & J. H. Riddle. UTACV-R-5064. FOARD Co. *ca.* 8 km N Crowell on TX.6. 13 October 1979. J. P. Karges, *et al.* UTACV-R-9295. HASKELL Co. 6.9 km W Rule on US 380. 27 April 1974. S. Wylie & L. Wylie. UTACV-R-2903. LUBBOCK Co. no precise locality. May 1973. L. A. Mitchell. UTACV-R-5535. SHACKLEFORD Co. 10.6 km N Albany on US 293. 2 August 1964. J. R. Glidewell. UTACV-R-2057.

Elaphe obsoleta lindheimeri (Texas Rat Snake): JONES Co. Stamford on TX.6. 27 April 1974. S. Wylie & L. Wylie. UTACV-R-2906.

Elaphe subocularis (Trans-Pecos Rat Snake): CROCKETT Co. 32 km (airline) S Ozona on TX. 163. 12 June 1968. J. E. Joy. UTACV-R-8665.

Heterodon nasicus (Western Hognose Snake): SCURRY Co. 59 km (by road) SE Post. 19 July 1964. J. R. Glidewell. UTACV-R-2092.

Heterodon platyrhinos (Eastern Hognose Snake): HOUSTON Co. 13.9 km SW Ratcliff. 31 March 1968. J. R. Glidewell & K. Barnes. UTACV-R-1425. KIMBLE Co. 54.8 km NE Rocksprings. 19 May 1973. R. W. Van Devender & J. R. Glidewell. UTACV-R-2700.

Lampropeltis getulus splendida (Desert Kingsnake): POTTER Co. Amarillo. September 1966. T. Hacker & J. R. Glidewell. UTACV-R-354.

Lampropeltis triangulum annulata (Mexican Milk Snake): JIM WELLS Co. 1.6 km S Premont. 18 August 1965. J. E. Joy. UTACV-R-8678.

Masticophis flagellum (Coachwhip): GARZA Co. 9.3 km E Post on US 380. 27 April 1974. S. Wylie & L. Wylie. UTACV-R-2892. RUNNELS Co. 7.1 km W Talpa on US 67. 16 May 1979. J. P. Karges, *et al.* UTACV-R-9182. SAN AUGUSTINE Co. 4.8 km N Broaddus on FM 1277. 20 May 1972. L. Rogers. UTACV-R-2547.

Masticophis taeniatus (Striped Whipsnake): COLEMAN Co. 0.4 km N Santa Anna. 28 July 1973. G. G. Riddle. UTACV-R-2620. FRIO Co. Dilley. 24 August 1964. W. F. Pyburn. UTACV-R-293.

Nerodia cyclopion (Green Water Snake): BRAZORIA Co. 8 km W Angleton. 21 August 1962. R. D. Burkett. UTACV-R-2214-2217.

Nerodia erythrogaster (Plainbelly Water Snake): SMITH Co. 8.8 km NE Lindale. 22 August 1962. H. W. Greene. UTACV-R-1374.

Nerodia fasciata confluens (Broad-banded Water Snake): ANGELINA Co. 3.2 km NW Broaddus. 10 May 1968. U.T.A. Nat. Hist. Class. UTACV-R-1455. HENDERSON Co. Waldrip's Lake, near Murchison. 31 August 1969. K. Barnes. UTACV-R-1584.

Nerodia rhombifera (Diamondback Water Snake): FOARD Co. *ca.* 8 km N Crowell on TX.6. 13 October 1979. J. P. Karges, *et al.* UTACV-R-9294. STEPHENS Co. NE part of county, no precise locality. 25 August 1951. W. E. Huffman. UTACV-R-1868.

Opheodrys aestivus (Rough Green Snake): KIMBLE Co. 1.6 km W Junction on US 377. 18 June 1977. D. B. Heckard. UTACV-R-6684.

Pituophis melanoleucus (Gopher Snake): COKE Co. 3.2 km W Robert Lee on TX.158. 16 May 1979. J. P. Karges, *et al.* UTACV-R-9027. COLLIN Co. 6.4 km SW McKinney on TX.121. 1 June 1975. J. L. Darling. UTACV-R-5242. COMANCHE Co. 28.4 km S Dublin on US 377. 16 May 1979. J. P. Karges, *et al.* UTACV-R-9026. JACK Co. 5.6 km SE Bryson. 6 May 1979. J. A. Campbell & L. S. Ford. UTACV-R-8719. LAMPASAS Co. 7.7 km SE Adamsville. 13 October 1974. J. R. Glidewell, *et al.* UTACV-R-5074. SAN SABA Co. 28.2 km W Lampasas at Colorado River, near Bend. 11 October 1974. U.T.A. Nat. Hist. Class. UTACV-R-5569.

Regina grahami (Graham's Crayfish Snake): CHAMBERS Co. Central part of county, no precise locality. 5 September 1953. W. E. Huffman. UTACV-R-127.

Rhinocheilus lecontei tessellatus (Texas Longnose Snake): POTTER Co. 11.3 km NE Bushland. 21 July 1963. J. R. Glidewell. UTACV-R-2107.

Salvadora deserticola (Big Bend Patchnose Snake): HUDSPETH Co. *ca.* 8 km WSW Hot Wells. 20 April 1974. S. R. Wylie. UTACV-R-5096.

Salvadora grahamiae lineata (Texas Patchnose Snake): ZAPATA Co. 9.7 km N San Ygnacio on US 83. No date given. H. W. Greene. UTACV-R-1512.

Sonora semiannulata (Ground Snake): HUDSPETH Co. Eagle Spring, 7.6 km WSW Hot Wells. 23 July 1976. J. R. Glidewell, *et al.* UTACV-R-8587. KINNEY Co. 37.1 km (airline) SW Brackettville. 12 April 1976. J. L. Darling. UTACV-R-7905. LLANO Co. 27.3 km S Llano. 26 December 1965. R. W. Van Devender. UTACV-R-50.

Storeria dekayi texana (Texas Brown Snake): SAN SABA Co. 4.8 km S, 2.7 km E Bend. 10 April 1976. J. L. Darling. UTACV-R-7885.

Tantilla gracilis (Flathead Snake): JIM WELLS Co. 2.4 km W Ben Bolt. April 1966. J. E. Joy. UTACV-R-8577.

Thamnophis cyrtopsis ocellata (Eastern Blackneck Garter Snake): WILLIAMSON Co. 11.3 km SW Georgetown. 7 April 1963. R. D. Burkett. UTACV-R-2329.

Thamnophis proximus (Western Ribbon Snake): YOUNG Co. Possum Kingdom Reservoir. 3 September 1950. W. E. Huffman. UTACV-R-1843.

Thamnophis sirtalis (Common Garter Snake): WHEELER Co. 26.6 km NW Shamrock. 11 April 1970. P. Ruff. UTACV-R-1899.

Virginia striatula (Rough Earth Snake): HOUSTON Co. 9.2 km N Ratcliff. 29 April 1966. U.T.A. Nat. Hist. Class. UTACV-R-1215. SAN SABA Co. 28.2 km W Lampasas at Colorado River, near Bend. 11 October 1974. U.T.A. Nat. Hist. Class. UTACV-R-5580.

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted. Citations should be sent to

Joseph Dinardo
Current Literature
16 Idlewild Road
Levittown, PA 19057

Current Literature has been cited by readers as a highly valued section of **HR.** If this is true, I'm baffled over the lack of response Joe Dinardo has gotten in his appeals for scanners. Response to his appeals in HR 12(3):74 were nil, and the current status is that he has **generated** half of each section himself in addition to preparing the section for publication. Two other major contributors are Joe Ideker (Edinburg, TX) and Heinz Wermuth (Germany). Without these three, Current Literature would be about as current as news of the Battle of Verdun. So, those of you who profess to value this section highly should give some quick thought to signing up as scanners. Yes, this will take some work, but ostensibly you scan some literature anyway — why not get a greater return on your time? In response to the obvious reply, to the effect that the present return on zero time is great, I offer this: It's totally inequitable to have these three persons pulling the whole load, and I have lots of manuscripts to run, so unless Joe gets some help, I'm planning to dump the section and save many people a lot of work. Titles for this month could not reach me in time, and will appear in June. I had planned to run a sample format card in this issue, but rather than do that and urge people to contribute willy-nilly to this section I decided instead to urge you to write to Joe and volunteer some time, and then to heed his directions carefully. Citation cards prepared illegibly and/or improperly cause nearly as much work as would an original search for that citation. So please, some consideration and help **if** you truly value this section.

COLOR PLATES OF FIJI CRESTED IGUANA AVAILABLE

A few dozen additional sets of the 2 color plates of Fiji iguanas (see **Journal of Herpetology** volume 15, number 3, July 1981) are available for purchase. Each plate has been signed personally by the artist, David M. Dennis; the plates measure 7 X 10 inches and would be quite suitable for framing.

Sets of 2 plates are available for a minimum donation of $15 postpaid by sending your check made out to "SSAR" to Henri C. Seibert, Department of Zoology, Ohio University, Athens, Ohio 45701. Donations in excess of the minimum are solicited as we are several hundred dollars short of the actual cost of printing the plates for the **Journal.**

NOTE: All persons who earlier donated to the Iguana color plate fund were sent complimentary copies in November 1981. Please notify us if these were not received. ●

AUSTRALASIAN AFFILIATION OF HERPETOLOGICAL SOCIETIES

The Affiliation started on an informal basis in 1974 and was formally established in 1977. Its objectives are to promote the scientific study of amphibians and reptiles and their conservation, to publish the journal *Herpetofauna*, to encourage liaison between the member societies through conventions, publications and field work, and to represent the interests of its member societies at the Regional level.

It is a non-profit co-operative organisation with the prime executive purpose of pooling the publishing resources of member herpetological societies in the Australasian Region. Five societies belong to the Affiliation (one in New Zealand and four in Australia) and another is considering joining. The Affiliation has a complimentary role and function to the Australian Society of Herpetologists in the Region.

PUBLICATIONS

Herpetofauna is published twice yearly and contains original papers and notes on any aspect of Australasian herpetology. Herpetological Notes, Regional News, and occasional book reviews are features of the journal. Member societies bulk subscribe to *Herpetofauna* on behalf of their members. Overseas and Australasian herpetologists who do not belong to one of the affiliated societies are invited to subscribe direct to the Affiliation. An Australasian herpetologists manual (of accumulated loose leaf design) on husbandry, study techniques, breeding, ailments etc. is in preparation.

MEETINGS

Conventions are held for society delegates and visitors about every two years in a field location, or hosted by a member society in its home city. Three productive and successful conventions have been held to date. The last was held in conjunction with the Melbourne Zoo Herpetological Symposium in May 1980. The fourth Convention will be in New Zealand in October, 1981. Societies from adjoining states also hold joint field work meetings.

INVITATION

Overseas and Australasian herpetologists who do not recieve *Herpetofauna* are invited to subscribe (use form below). Back issues are available. Readers of Herpetological Review who subscribe will receive their first copy free with six to follow.

The Editor,
The Australasian Affiliation of
Herpetological Societies,
Box R307 Royal Exchange,
SYDNEY. N.S.W. 2000. AUSTRALIA.

Please find enclosed cheque, money order, postal note, etc. to the value of *Aust. $10.00 or $15.00 for six issues of *Herpetofauna* published twice yearly.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the editor.

SSAR BUSINESS

THANKS DUE

The SSAR Officers, Board of Directors and membership are most grateful to the following persons who have served the Society during the past year:

Robin M. Andrews
Ray E. Ashton, Jr.
James L. Christiansen
Roger Conant
Herbert C. Dessauer
Douglas F. Fraser
Darrell R. Frost
J. Whitfield Gibbons
James C. Gillingham
John D. Groves
James E. Huheey
John B. Iverson
James S. Jacob
Jerry D. Johnson
James L. Knight
Edward Moll
John C. Murphy
Michael V. Plummer
Eric M. Rundquist
Hobert M. Smith
Priscilla H. Starrett
Margaret M. Stewart
Robert A. Thomas
Harold K. Voris
Laurie J. Vitt
Robert G. Webb ●

A LETTER TO SSAR MEMBERS AND OFFICERS

Effective 1 January 1982 I shall resign as Secretary of the Society for the Study of Amphibians and Reptiles. I have served the SSAR, in some capacity, since 1961 when I first became Secretary of its predecessor, the Ohio Herpetological Society. I derive satisfaction from having played a part in watching the Society grow from a few members in 1961 to the largest international herpetological society in the world today.

I count it fortunate to have been associated with many colleagues during those twenty-one years, and particularly enjoyed my interactions and friendships with Kraig Adler and Henri Seibert. Both have served the SSAR longer than I have, and we have spent many stimulating hours cussing and discussing various aspects of Society operations. We often were not in philosophic agreement, but apparently the mix of our ideas and philosophies did not harm the SSAR, and may have even contributed to some of its success. During the last fourteen years, beginning with my move from Ohio to Kansas, my involvement with the SSAR has been enthusiastically supported by the Director of my Museum, Philip S. Humphrey. His support of my SSAR activities has been considerable and good, and has made my SSAR involvement much less time-consuming.

The SSAR today is, in my opinion, the successful result of a particular philosophy unique to it as an international herpetological organization. Quite simply, the SSAR defines herpetology and the herpetological community in the broadest possible sense, and attempts to serve that constituency. The success of this philosophy is evident in the SSAR's large membership, diverse products and services, and well-attended annual meetings. I do not think that any other herpetological society in the world can approach the success of the SSAR without adopting this philosophy, and I hope that future officers of SSAR never forget that the Society's strength, diversity and success derive from the broad-based support it receives from herpetologists associated with zoos, regional herpetological societies, state and Federal wildlife agencies, non-University museums, nature centers, private research foundations, and particularly from enthusiastic individuals whose only herpetological credentials are an interest in amphibians and reptiles.

See you all next August at the SSAR Silver Anniversary meeting in Raleigh, North Carolina.

JOSEPH T. COLLINS ●

SSAR ELECTION RESULTS

One hundred and twenty SSAR members responded to the mail ballot sent out with **Herp. Review** 12(3) to elect 1981 officers. The following individuals were elected:

President-elect:	Ralph W. Axtell
Secretary:	Joseph T. Collins[1]
Treasurer:	Henri C. Seibert
Board of Directors: (Class of 1984)	Thomas Fritts Norman J. Scott

The SSAR thanks all candidates for accepting the nomination to run for SSAR office. In addition, the Society is grateful to David G. Baker, Dallas Zoo, for ably serving as SSAR elector for 1981.

[1]Joseph T. Collins has since resigned as SSAR secretary effective 1 January 1982. The SSAR Board of Directors has appointed James Jacob, Memphis State University, to serve Collins' 1982 term as SSAR secretary.

●

COLOR PLATES OF FIJI CRESTED IGUANA AVAILABLE

A few dozen additional sets of the 2 color plates of Fiji iguanas (see **Journal of Herpetology** volume 15, number 3, July 1981) are available for purchase. Each plate has been signed personally by the artist, David M. Dennis; the plates measure 7 X 10 inches and would be quite suitable for framing.

Sets of 2 plates are available for a minimum donation of $15 postpaid by sending your check made out to "SSAR" to Henri C. Seibert, Department of Zoology, Ohio University, Athens, Ohio 45701. Donations in excess of the minimum are solicited as we are several hundred dollars short of the actual cost of printing the plates for the **Journal.** ●

REPRODUCTIVE BIOLOGY OF REPTILES SYMPOSIUM VIDEOTAPES AVAILABLE

Color Betamax® videotapes of the 22 presentations at the Symposium on Reproductive Biology of Reptiles (held in conjunction with the 1981 joint annual SSAR/HL meeting at Memphis State University) are available for loan. Have your institution's library contact Interlibrary Loan, John W. Brister Library, Memphis State University, Memphis, TN 38152 and request specific presentations.

The tapes will be available for one week of in-library use only. If videotape players are unavailable in your library, use by requesting individual will be at the discretion of the borrowing library. Copies can be made by the borrowing institution as long as they are for educational use and are not sold. Contact James S. Jacob (Department of Biology, Memphis State University, Memphis, TN 38152) for a list of titles, or if you need further information. ●

PROCEEDINGS OF THE 1981 SSAR GENERAL BUSINESS MEETING AT MEMPHIS STATE UNIVERSITY

The annual general business meeting of the SSAR was called to order by President James B. Murphy at 4:45 PM on 11 August 1981 in the University Center Ballroom at Memphis State University.

President Murphy welcomed attending SSAR members to the business meeting, pointed out the wide variety of services and products provided by the Society to its membership, and encouraged members to volunteer for positions on Society committees in order to ensure active and meaningful membership participation in future Society programs.

Joseph Collins presented a brief report on the activities of the SSAR Secretary. President Murphy received a motion to approve the minutes of the 1980 SSAR General Business Meeting from Carl Gans (seconded by Ralph Axtell), and the motion passed unanimously.

Henri Seibert presented a concise report on the activities of the office of SSAR Treasurer, pointing out the many benefits that SSAR members receive, and announcing that non-U.S. memberships and subscriptions would have a $5.00 postal surcharge added to them effective 1 January 1982. Seibert further announced that, effective 1 January 1982, subscription to the Catalog of American Amphibians and Reptiles would increase to $10.00 for individuals and $15.00 for institutions.

President Murphy then called on the various Society editors for brief reports, the highlights of which were that: 1) Rodolfo

Ruibal announced the transfer of printing of the **Journal of Herpetology** from the current printer to Allen Press, Lawrence, Kansas, effective with volume 16; 2) Kraig Adler announced that, because of economy measures, no free small facsimile reprints would be issued during 1982; and 3) Adler presented a series of color slides showing illustrations which will appear in a book on Venezuelan turtles which the Society hopes to publish in the SSAR **Contributions to Herpetology** series in the near future.

President Murphy then called on the various SSAR committee chairpersons for brief reports, the highlights of which were that: 1) Kraig Adler announced that the SSAR will hold its 1983 annual meeting at the University of Utah, Salt Lake City: 2) Joseph Collins reported that his committee had completed preparing a second edition of "Common and Scientific Names for North American Amphibians and Reptiles," to be published as a **Herpetological Circular** by the SSAR in 1982, and that the **Herpetological Circular** series would no longer be sent free to the membership, but that members would have the opportunity to obtain this series at a reduced pre-publication price; 3) Martin Rosenberg announced the recipients of the SSAR Grants-In-Herpetology (see **Herp Review**); and 4) Michael Plummer announced the recipient of the 1981 Kennedy Award (see **Herp Review**).

Nominating Committee chairperson Jerry D. Johnson then presented the slate of nominees for 1982 SSAR offices, as follows:

For President-elect:	Ralph W. Axtell Thomas A. Jenssen
For Secretary:	Joseph T. Collins
For Treasurer:	Henri C. Seibert
For Board of Directors:	Robin Andrews Thomas H. Fritts Norman J. Scott Craig Weatherby

There being no nominations from the floor, President Murphy received a motion from Margaret M. Stewart (seconded by Patricia Riexinger) that the nominations be closed, and the motion passed unanimously.

President Murphy then called for additional reports, as follow: 1) Kraig Adler and Ray Ashton gave a slide presentation and report on the 1982 SSAR Silver Anniversary Meeting to be held at Raleigh, North Carolina, in August; 2) Joseph Collins reported that the constitutional amendment to the SSAR Bylaws, which would permit the SSAR Board of Directors to set dues for the Society, would be mailed this fall with the election ballots; 3) Arthur C. Echternacht announced that new guidelines had been established for symposia to be presented at future SSAR meetings; and 4) Kraig Adler reported that he would soon be in England to confer with the British Herpetological Society on a proposed arrangement by the BHS to adopt the **Journal of Herpetology** as their technical periodical.

President Murphy then yielded the floor to the Resolutions Committee, composed of Robert A. Thomas, Thomas H. Fritts, W. Ronald Heyer and Frances Irish, and Thomas (sometimes known as the New Orleans cowboy) presented the following resolutions:

1. **Whereas,** the 1981 Annual Meeting of the SSAR/HL was hosted by Memphis State University and the attending herpetologists have benefitted from the diligence, imagination and creativity of an esteemed local meeting committee, and

   Whereas, the coordination of the meetings has been superbly orchestrated, and

   Whereas, the facilities and academic ambience have been exceptionally conducive to the exchange of ideas and information on which the meetings are based, and

   Whereas, several organizations and individuals have cooperated to make the meeting a success, and

   Whereas, the office of the University Conference Coordinator substantially supported the meeting and the symposium, then

   Be It Resolved, that the officers and members of the SSAR/HL express their sincere gratitude to James S. Jacob, committee chairperson, and the following local committee members: George D. Baumgardner, Jack Cassidy, James Detterline, Jack Greenhaw, Leslie Johnson, Butch Odum, Sam Reynolds, Steve Sanders, and Richard Smith.

The resolution was adopted unanimously to enthusiastic applause.

2. **Whereas,** James L. Christiansen has effectively and capably carried out the responsibilities of the office of SSAR Assistant Publications Secretary, and

   Whereas, he has served in this capacity for eleven years, and

   Whereas, he will retire from this SSAR office at the end of 1981, then

   Be It Resolved, that the officers and members of the SSAR express their sincere gratitude to Jim Christiansen for his dedication and service to the Society on the occasion of its 24th annual meeting.

The resolution was adopted unanimously to abundant applause.

3. **Whereas,** Ernest E. Williams has provided the first HL Distinguished Herpetologist's Lecture summarizing his long and distinguished participation in anoloid research, then

   Be It Resolved, that the attendees of the SSAR/HL meeting express their sincere gratitude to Ernest Williams for putting our anoloid house in better order.

The resolution was adopted unanimously to resounding applause.

4. **Whereas,** the sober deliberations of the staid herpetologists in the Memphis State University housing led to an atmosphere of stable equilibrium, and

   Whereas, this equilibrium was punctuated by the tribal chants and dances of nomadic hordes in colorful, but abbreviated, native costumes, and

   Whereas, the customs of these both muscular and nubile chanters and dancers are foreign to the somber ways of herpetologists, and

   Whereas, said chanters and dancers are in need of close scientific evaluation to determine how so many bodies could possibly be free of zits, then

   Be It Resolved, that all future SSAR meetings hosting both herpetologists and cheerleaders be organized to ensure that each herpetologist is provided her or his choice of a cheerleader roommate.

The resolution was adopted to lusty applause.

5. **Whereas,** the meeting participants have come to Memphis from diverse geographic areas, and

   Whereas, these participants might forget where they are at night, then

   Be It Resolved, that the SSAR express its appreciation to Memphis State University for supplying cockroaches to each and every room in Richardson Towers, said small creatures to serve as reminders that Memphis is in the South.

The resolution was adopted to repulsive applause.

6. **Whereas,** the survey (requested of Jim Jacob in 1980 at Milwaukee) of Memphis honky-tonks and rock-and-roll dance halls has been provided and judged adequate by a distinguished panel of jurors, then

   Be It Resolved, that the herpetologists gathered in Memphis join the movement supporting the placement of the City of Memphis in the Texas Hall of Fame.

The resolution was adopted by selected applause from Robert Thomas and James B. Murphy.

President Murphy then yielded the floor to Joseph Collins for the presentation of a resolution adopted by the SSAR Board, as follows:

> "The Society for the Study of Amphibians and Reptiles actively discourages general collecting at the time of its annual meeting. Persons should have **bona fide** scientific or educational rea-

sons to collect and retain specimens, and then must have the necessary local, state and Federal permits to do so. Instead, photographs are recommended as a viable alternative to preserved specimens, although care must be taken not to harm animals or damage their habitat."

Steve Roble moved (seconded by Ray Ashton) the adoption of this resolution by the assembled SSAR members, and the resolution was adopted unanimously.

President Murphy then yielded the floor to Ray Ashton for the presentation of a resolution, as follows:

> **Whereas,** Secretary of the Interior Watt has publicly stated and is following a policy detrimental to the conservation of amphibians and reptiles, and habitats critical to their existence, then,
>
> **Be It Resolved,** that the SSAR take a formal stand in requesting his removal from office, and that a letter to this effect be sent to President Ronald Reagan and to the chairpersons of the appropriate legislative committees of the U.S. House of Representatives and the U.S. Senate.

It was moved by Steven Buth (seconded by Thomas Jenssen) to adopt the resolution. President Murphy opened the floor for discussion, and various members presented their views. There being disagreement among the assembled membership over the wording of the resolution, Edmund Brodie moved (seconded by Carl Gans) that the resolution be tabled for presentation to the SSAR Board at next year's meeting. The motion to table the resolution passed.

President Murphy then introduced Kraig Adler, who will assume the SSAR presidency for 1982, and presented him with the sacred SSAR gavel, but not before pounding the meeting adjourned.

Respectfully submitted,

JOSEPH T. COLLINS
SSAR Secretary ●

1981 SSAR GRANTS-IN-HERPETOLOGY AWARDS

The Society for the Study of Amphibians and Reptiles is pleased to announce the following awards in the 1981 Grants-In-Herpetology Program:

GRADUATE STUDENT RESEARCH:

James E. Lynch Jr., Department of Biological Sciences, University of Idaho, Moscow. "Induced Ovulation in the Coeur d'Alene Salamander." $187.

Charles R. Crumly, Department of Zoology and Physiology, Rutgers-The State University. "The Inter- and Intrageneric Relationships of Tortoises (Testudinidae): A Survey and Re-Evaluation of Anatomical Systems." $166.

HERPETOLOGICAL CONSERVATION:

Dr. Myrna E. Watanabe, New York College of Podiatric Medicine. "The Chinese Alligator *(Alligator sinensis):* A Behavioral Study and Population Survey." $315.

HERPETOLOGICAL RESEARCH IN ZOOS:

Stanley Held, Washington Park Zoo, Portland, Oregon. "Investigation Into Maintaining, Breeding and Exhibiting the Tailed Frog, *Ascaphus truei,* in a Zoological Park." $250.

Steve Connors, Cheyenne Mountain Zoological Park, Colorado Springs, Colorado. "The Effect of Temperature and Photoperiod on Reproduction in Snakes." $65.

REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS:

No proposals were received.

SSAR extends its congratulations to all recipients of awards and encourages the submission of proposals for next year's program. SSAR also expresses its thanks to the 1981 Grants-In-Herpetology Committee, composed of: Martin J. Rosenberg (Chairperson), Ralph W. Axtell (Graduate Student Research), Douglas Fraser (Regional Herpetological Society Programs), Terry E. Graham (Conservation Research), and John D. Groves (Herpetological Research in Zoos). ●

Federal Regulations Regarding the Transport Of Formalin Aboard Passenger Aircraft

Formalin is often carried as accompanied baggage aboard passenger aircraft by those of us who require voucher specimens as documentation of our field projects. The Federal government includes Formalin in the hazard class ORM-A (49CFR172.101) and regulates quantity, labeling, and packaging for legal transportation aboard passenger aircraft. Failure to comply with these regulations subjects the guilty party to a maximum penalty of $10,000 for each infraction of FAA regulations. In the following paragraphs, I have attempted to present the essence of the regulations in a language with which most of us are comfortable.

While no hazard labels (corrosive, flammable, etc.) are required, 10 gallons of Formalin is the maximum net quantity which may be carried in one package aboard a passenger airplane. Two copies of the following document (shipping papers) must be presented to the airline (previous to check-in, I presume):

This shipment contains **FORMALDEHYDE,** ORM-A, in the amount (insert amount).
I hereby certify that the contents of this consignment are fully and accurately described above by proper shipping name and are classified, packed, marked and labeled, and in proper condition for carriage by air according to applicable national governmental regulations. This shipment is within the limitations prescribed for passenger aircraft.

(Legible signature)

(49CFR172.202, 49CFR172.204).

Baggage containing Formalin must be marked: **FORMALDEHYDE, ORM-A, (amount)** in English, with a "durable" substance, printed on or affixed to the surface, or on a rectangular label, tag, or sign. This label **must be** displayed on a background of sharply contrasting color unobscured by labels or attachments and located away from any other marking which substantially reduces its effectiveness; name and address of consignee are also required on this label. This package must be packed with closures upward and legibly marked "This Side Up" with an arrow symbol indicating direction (49CFR172.304, 49CFR 172.306, 49CFR172.312a).

The inside container must also be plainly and durably marked on at least one end with the ORM-A designation (ORM-A must be placed within a rectangle 0.25 in [6.3 mm] larger on each side than the designation) immediately following the name FORMALDEHYDE (49CFR172.316a). Each package containing Formalin must be designed and constructed to prevent leakage caused by changes in altitude and temperature during air transportation.

Containers in direct contact with Formalin (i.e. the bottle) must also be packaged to prevent leakage and breakage under conditions "normally incident to transportation . . . (which means) capable of withstanding a 4 foot drop on solid concrete in the position most likely to cause damage." Plastic bags or pouches are not permitted.

Sufficient outage (ullage) must be provided to prevent liquid contents from completely filling the packaging at 130° F (55° C). The Formalin container must be capable of withstanding, without leakage, an internal absolute pressure of no less than 26 lbs/sq in or no less than the sum of the absolute vapor pressure of the contents at 130° F and the atmospheric pressure at sea level, whichever is greater. Screw type closures must be secured to prevent loosening due to vibration or changes in temperature (49CFR173.6).

There is an official of the FAA at most large airports who is empowered to interpret these regulations; I advise anybody carrying Formalin in his baggage to get an official approval (in writing) before boarding the aircraft.

1982 JOINT ANNUAL MEETING

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

25th Anniversary Meeting

HERPETOLOGISTS' LEAGUE

30th Annual Meeting

Raleigh, North Carolina: State Museum of Natural History
1–6 August 1982

HL DISTINGUISHED HERPETOLOGIST LECTURE:

Thomas Uzzell (Academy of Natural Sciences, Philadelphia).

SSAR SILVER ANNIVERSARY SYMPOSIUM:

"MOLECULAR AND GENOMIC EVOLUTION OF AMPHIBIANS AND REPTILES"

David B. Wake (University of California at Berkeley), Organizer and Moderator.

This special symposium will focus on current questions concerning population structure and gene flow, species problems and relationships of taxa, and will include an overview of the newest techniques and approaches with a look to the future. The 30 participants, comprising the leading authorities from Europe and North America, will cover these topics in several keynote lectures, research papers and public discussion sessions.

TECHNICAL PAPER PRESENTATIONS

Research reports will be given in two formats: oral presentations (with several concurrent sessions) and poster sessions.

SOCIAL ACTIVITIES

Several evening events are planned, highlighted by a genuine Old Fashioned Carolina Pig Pickin' and Barbeque.

FIELD TRIPS

Several trips will be scheduled following the meeting to the North Carolina Coastal Plain and Green Swamp and to the Blue Ridge Mountains and Great Smoky Mountains. Collecting of specimens will not be permitted, only photography.

DISPLAYS

1. "Herpetological Art and Photograph Display", including contest.
2. "Amphibians of the Appalachian Mountains", a multimedia sound-and-slide presentation by David M. Dennis and Eric Juterbock.
3. "Live Amphibians and Reptiles of the Carolinas", a display sponsored by the North Carolina Herpetological Society. Photography will be permitted.
4. "Herpetologists Then and Now", a slide show organized by David M. Dennis.
5. Displays of Herpetological Films, Books and Equipment.

WORKSHOPS

1. "Program Funding, Administration and the Practicalities of Running a Regional Herpetological Society", sponsored by the SSAR Regional Society Liaison Committee and the North Carolina Herpetological Society.
2. "Gopher Tortoise Council", arranged by Richard Franz.
3. "Photography Workshop", a how-to-do-it session arranged by David M. Dennis.
4. "Funding Sources for Herpetological Research", sponsored by the SSAR Zoo Liaison Committee.

●

ADDITIONAL INFORMATION

A detailed Program and Call for Papers will appear in *Herpetological Review* and in *Herpetologica*. For other details write Ray E. Ashton, North Carolina Museum of Natural History, P.O. Box 27647, Raleigh, North Carolina, 27611, U.S.A. All interested persons are welcome to attend.

BRITISH HERPETOLOGICAL SOCIETY

EVENING MEETINGS 1982

The meetings start at 7:00 p.m. and are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1, unless otherwise indicated. SSAR members passing through London during 1982 will be very welcome in celebration of the U.S. Society's 25th Anniversary Year.

February 23rd.
Mr. S. SPAWLS: Structure and ecology of a savannah population of snakes in northern Ghana (West Africa).

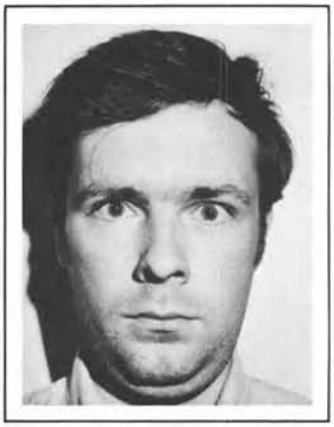
March 23rd.
Annual General Meeting, followed by Dr. H. R. BUSTARD (FAC Crocodile Breeding Project, India): Conservation of the Indian gharial.

April 22nd.
Dr. I. R. SWINGLAND, Chairman, IUCN/SSC Tortoise Group: A report on the Inaugural Meeting in Oxford, 1-2 October 1981; Dr. M.R.K. LAMBERT (IUCN/SSC Tortoise Group — West Palaearctic species): A report on the 2nd European Chelonian Symposium, Oxford, 3-4 October 1981, and Mr. M. L. HINE: *Testudo marginata* in the Pelopponese (S. Greece) and their captive management in Britain.

May 19th.
Prof. G.A.D. HASLEWOOD: Free-living lizards in a Sussex garden (S. England).

June 15th.
**Amphibians and reptiles of the Old World.* A discussion on the care and breeding with the BHS Captive Breeding Committee.

July 7th.
A visit to the London Zoo. A meeting organised by the BHS Captive Breeding Committee during a Members' Evening of the Zoological Society of London. BHS members should meet at the Fellows' Entrance in the Outer Circle of Regent's Park. If late, please tell the Gateman you are with Mr. S. TOWNSON.



September 22nd.
**Amphibians and reptiles of the New World.* Details as for June 15th.

October 26th.
Prof. J. I. MENZIES (BHS Secretary 1952-7, lately Dept. Zoology, Univ. Papua New Guinea): Trouble with frogs, a taxonomist's problems in New Guinea.

November 24th.
Dr. B. GROOMBRIDGE (Editor, IUCN Red Data Book: Amphibia & Reptilia, SCMU, Cambridge): Compiling information on threatened amphibians and reptiles.

*Members should bring live animals, preserved specimens and 35 mm colour slides for display and to illustrate discussions.

WANTED

SLIDES of HERPETOLOGISTS

I AM PREPARING A MULTI-SCREEN SLIDE SHOW ENTITLED "HERPETOLOGISTS THEN AND NOW", WHICH WILL BE PRESENTED DURING THE 25TH ANNIVERSARY MEETING IN RALEIGH.

YOUR HELP IS VITAL TO THE PRODUCTION OF A GOOD SHOW. I NEED SLIDES OF AS MANY HERPETOLOGISTS AS POSSIBLE. IF YOU HAVE FUNNY OR EMBARRASSING SLIDES (NO PORNO PLEASE!) SEND THEM TO DAVID DENNIS, DEPARTMENT OF BOTANY, THE OHIO STATE UNIVERSITY, 1060 CARMACK ROAD, COLUMBUS, OHIO 43210.

YOUR SLIDES WILL BE HANDLED WITH EXTREME CARE, AND RETURNED PROMPTLY AFTER THOSE CHOSEN FOR THE SHOW HAVE BEEN DUPLICATED.

REMEMBER, YOUR FRIENDS WILL BE SENDING SLIDES OF YOU!

P.S. I CAN ALSO USE BLACK AND WHITE AND COLOR PRINTS!

GRAD STUDENTS! YOUR ANONYMITY WILL BE PRESERVED.

A Suggested Protective Declaration for Taxonomic Dissertations

In recent years the information in doctoral and other dissertations has become quickly and readily available to interested workers, primarily through Dissertation Abstracts and local or commercial reproduction facilities. Often dissertations are, quite in error, considered as publications even by their authors, particularly when compiling their curricula vitae with the expected list of publications. Thus new names and name combinations sometimes, usually inadvertently, appear in legitimate, scientific publications before the real originator publishes them. In such circumstances the nomenclatural novelties often must be credited, under the Law of Priority of the International Code of Zoological Nomenclature, to the inadvertent user, to his or her intense embarrassment and to the dismay of the unpublished originator. The injustice can be reversed in some instances by appeal to the International Commission on Zoological Nomenclature, but not always are the appeals successful, and invariably they are protracted and laborious.

Several instances that have come to my attention in recent years suggest that the problem is widespread and growing. Explicit attention needs to be called to it in order to forestall insofar as possible its unfortunate results.

A possible step in that direction is the inclusion, preceding the body of every taxonomic dissertation, of an explicit notice warning of the confidentiality of the information contained therein. A suggested form follows.

NOTICE

According to the International Code of Zoological Nomenclature (Art. 9), dissertations submitted in partial fulfillment of requirements for doctoral, master's or other degrees do not constitute publications in the nomenclatural sense, even when reproduced on microcards, by microfilm or other similar methods. Therefore the novel names or name-combinations proposed in taxonomic dissertations are not thereby entered into the public domain. The information given in such works is in effect confidential in scientific contexts and cannot ethically be utilized by anyone in any (Art. 8 of the Code) publication until the author of the dissertation has published it in a legitimate outlet (even Dissertation Abstracts may serve), unless the author or the author's adviser gives permission for someone else to do so, or unless after a reasonable interval neither can be consulted even with concerted effort (in conformance with the Code of Ethics, Appendix A of the International Code of Zoological Nomenclature).

Protection under the articles and appendices of the Code is hereby claimed for this dissertation.

CHECKLIST OF THE AMPHIBIANS AND REPTILES OF THE WORLD

The Association of Systematics Collections (ASC) is producing a checklist of the amphibians and reptiles of the world to be published when completed. The information to be carried with each species record will be: current name (following most recent literature), original name, author, type locality, deposition and museum number of type (when readily available), distribution, comment citing taxonomic controversy (if necessary) and revisory literature, and regulatory status under U.S. laws and international agreements. The intended purpose of this checklist is to provide ready access to the literature of systematic herpetology as well as much of the information that is necessary for taxonomic work. The legal information provided should make life a little easier for workers who collect specimens or send and receive loans of specimens. At this time we are soliciting unpublished checklists as well as other contributions from volunteers for possible inclusion into the ASC Checklist. Contributors will be acknowledged in the published checklist at the taxonomic level of their contribution, as will reviewers. The editorial committee for this undertaking is comprised of William E. Duellman, Chairman (Museum of Natural History, University of Kansas), Robert Drewes (California Academy of Sciences), Carl Gans (University of Michigan), Alice Grandison (British Museum of Natural History), and Marinus Hoogmoed (Rijkmuseum van Natuurlijke Histoire, Leiden). All correspondence should be addressed to Darrel Frost (Editor), Museum of Natural History, The University of Kansas, Lawrence, KS 66044. ●

ENSIL ROSS ALLEN
1908-1981

Ross Allen, showman, athlete, and one of Florida's best known and most respected celebrities, died of cancer 17 May 1981 about a month prior to the opening of his long-planned Alligator Town, U.S.A. at Lake City. That tourist attraction was to be the culmination of his lifetime of work in handling and demonstrating reptiles.

Most persons who knew Allen will remember him as a handsome, soft-spoken, friendly, obliging man for whom nothing was too much trouble, especially if it concerned wildlife. Those of us who worked with him, particularly in the field, appreciated his wide knowledge of the reptiles of Florida and the help he invariably gave any herpetologist who needed specimens or information.

Allen was born in Pittsburgh, Pennsylvania, on 2 January 1908. His family moved to Winter Haven, Florida, when he was 16, and there he soon began assembling a private menagerie which, after graduating from high school and attending Stetson University for a year, he transferred to Silver Springs. His collection became the nucleus of what later was named, at the request of others, The Ross Allen Reptile Institute, and there he held sway for 46 years.

He had been milking snakes and selling the venom for some years, but at Silver Springs he made the extraction process pay double by doing it in view of groups of cash customers, largely tourists, who were fascinated by the process and by his down-to-earth talks about the snakes and other exhibits. For decades he was the chief supplier of diamondback rattlesnake and cottonmouth venom, but he greatly stepped up production prior to America's entrance into World War II, when Wyeth, Inc., of Philadelphia, was called upon to produce large quantities of antivenin for troops on maneuvers in the Southern States.

Because he was a powerful swimmer endowed with a splendid physique, Allen early learned how to capture alligators in their natural environment, wrestling them to the surface and then on shore. Handling 'gators became a natural part of his demonstration at the Reptile Institute.

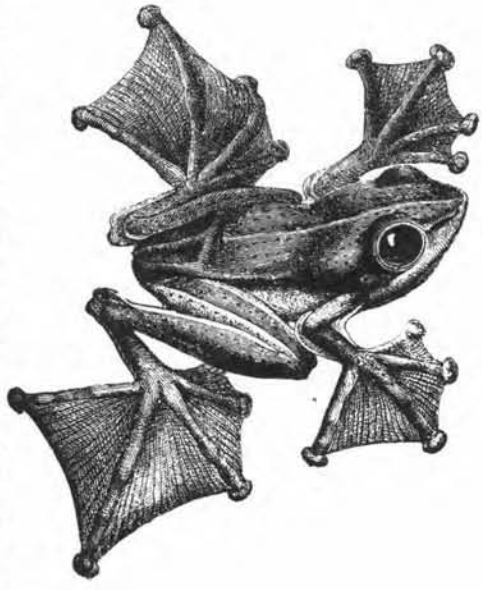
Ross enrolled as a Boy Scout at an early age, and he retained interest in that organization throughout his life and received several of scouting's highest awards. One was given in recognition of his leadership and woodsmanship during a cross-Florida trek, from Daytona Beach to Yankeetown on the Gulf of Mexico, with eight boys, during which they lived exclusively off the land. They made the 153 miles in 13 days. Allen was 54 at the time. He delighted in working with young people and teaching them about wildlife. He sired seven children of his own, the youngest of whom was born when he was 61.

During his long career he led several trips to Latin American countries to bring back live specimens for his collection, including new

species of frogs. A large and colorful rat snake, *Elaphe obsoleta rossalleni,* bears his name.

Concurrent with his rising fame and because he was highly photogenic, Allen was much in demand for motion picture parts and, later, for television. He appeared in a number of films and on most of the regular TV series concerned with natural history or adventure.

All his life Ross Allen wanted to be a scientist, but he knew his limitations. Once, when we were in the field together in the Upper Florida Keys, he confided in me by saying, "I know I'm not college material and I'm a poor writer, but I love herpetology and want to do everything I can to further it, even if all I manage is to take you and others into the field and help by finding specimens for whoever needs them." He was as good as his word, and sent many of us snakes and other reptiles for study, always claiming they were surplus and were gifts for which no compensation was expected.



Despite his comments, Ross Allen's name appeared on many newspaper and magazine articles as well as on papers in herpetology. The majority, however, were co-authored, most of the more technical ones with the knowledgeable Wilfred T. Neill, who joined Allen at the Reptile Institute at Silver Springs for several years. Together they assembled a well-preserved study collection, specimens from which were designated as ERA-WTN from their combined initials.

It was probably inevitable that, while handling large numbers of venomous snakes, Ross would be bitten. Indeed, he sustained 12 bites, some of them extremely serious. Invariably he returned to work as soon as possible instead of abdicating, so to speak, and allowing the assistants, whom he had trained, to continue alone.

After his long tenure at Silver Springs, Allen went into retirement for a short time, but he soon emerged to become associated, first with the Sarasota Jungle Gardens and then with the Alligator Farm at St. Augustine. Above all, however, he wanted his own place, a life-long desire that came close to fulfillment. Such was to be Alligator Town at Lake City. As a naturalist he was annoyed with the crass indifference toward wildlife shown by so many Floridians, and especially the retirees who flooded into the area from the northern states during recent years. Also, as a person who had devoted his life to animals, he was upset by the tinsel and glitter surrounding such more recent attractions as Disney World, with their rides and other amusements. He was determined to prove there was still a place for the old-time showman, and that poisonous snakes and 'gators had not lost their glamour. He designed his dream exhibit and supervised its construction until rapidly declining health terminated his career. One can readily imagine the deep feeling of frustration that must have pervaded his final days as he realized he would not be on hand to preside over it.

Ross Allen had charisma, he was an excellent raconteur, and he had millions of admirers, thanks to his long career at various Florida institutions and the magic of television. Those of us who were his close friends will always think of him as an outstanding herpetologist who was distinguished from all others in his own inimitable and natural way.

ANNOUNCES

Amphibians and Reptiles in Kansas

By Joseph T. Collins **Second (Revised) Edition**

To be issued in early spring 1982, this softbound volume is a thorough update of the 1974 edition, with new sections on alien species, introductions to the main groups, endangered species, an extensive and fully illustrated technical key, and an updated bibliography to the Kansas herpetofauna. In addition, the range maps have been enhanced by the addition of over 525 new county records obtained since 1974, and most of the 150 black and white photographs are new.

NEWSNOTES

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1982 Grants-In-Herpetology Program. This Program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. Grant proposals will be considered in the following areas:

1) HERPETOLOGY-ORIENTED CONSERVATION. Proposals should address research on endangered or threatened species at the state, national or international levels, or address research on critical herpetological habitats. Proposals may be received from individuals only.
2) GRADUATE STUDENT HERPETOLOGICAL RESEARCH. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.
3) REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individual members of the society. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.
4) HERPETOLOGICAL RESEARCH IN ZOOS. Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.

Each proposal should include the following information: A) **Background & Objectives** of the proposed project, in terms of its relevance to herpetology, B) **Methods** of carrying out the research or conducting the project, C) **Budget** for the project, which should not exceed $400 in each category, and D) **Letter of Support** (if applicable). Proposals should be relatively brief (approx. 5 typed pages).

Successful applicants will be expected to submit to SSAR a written report of the results of their research or project, within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to **The Journal of Herpetology** or **Herpetological Review.**

Members of the SSAR Grants-In-Herpetology Committee will evaluate all proposals, projects or programs. Committee members are: Martin J. Rosenberg (Chairperson), Terry E. Graham (Conservation Research), John B. Iverson (Regional Herpetological Society Projects), Linda R. Maxson (Graduate Student Research), and Lyndon A. Mitchell (Zoo Research).

Individuals submitting proposals should designate to which of the four areas their proposal applies. All proposals must be typewritten and submitted in duplicate no later than **15 APRIL 1982** to:

Martin J. Rosenberg
Department of Biology
Case Western Reserve University
Cleveland, Ohio 44106

1980 KENNEDY AWARD WINNERS

The 1980 Kennedy Award Committee has determined that the paper "Responses of Five-Lined Skins *(Eumeces fasciatus)* and Ground Skinks *(Scincella lateralis)* to Conspecific and Interspecific Chemical Cues," authored by David Duvall, Renée Herskowitz and Jeanne Trupiano-Duvall, was the best student paper published in Volume 14 (1980) of the *Journal of Herpetology*. For their efforts the authors were awarded a $100 check and a set of David Dennis' herpetological prints at the SSAR business meeting in Memphis, TN, 11 August 1981.

Congratulations to these students from the Kennedy Award Committee, which consisted of Robin Andrews, Alan Channing, Darrell Frost, John Iverson and Mike Plummer.

NSF SURVEY

The Division of Environmental Biology of the National Science Foundation (NSF) is evaluating how the Systematic Biology and Biological Research Resources programs might better serve the systematic biology community in the U.S. Two surveys, developed by the Association of Systematics Collections (ASC) under contract with NSF, will gather data concerning the physical resources available to the research community and demographic information on the individuals who comprise the community.

The first survey, to be mailed to collection curators and managers in November, 1981, will request information regarding the management, the financial resources available for support, the services provided, and the future needs of their collections. The second survey, to be mailed in July, 1982, will collect data on individual systematic biologists.

All curators and collection managers now have an opportunity to contribute to the development of the long-term policies and goals of NSF. To assure that the community has an opportunity for further comment, a preliminary report of the results of the survey will be presented at the ASC annual meeting in May, 1982. If you do not receive a survey form by November 15, 1981, please contact:

Nancy J. Wert
NSF Project Coordinator
Association of Systematics Collections
Museum of Natural History
University of Kansas
Lawrence, Kansas 66045
(913) 864-4867

When requesting a survey form, please indicate the taxonomic emphasis of your collection. ●

BAT CAVE LEASED BY NATURE CONSERVANCY

The Nature Conservancy has acquired through lease the 92-acre Bat Cave tract in Henderson and Rutherford Counties, North Carolina. Among the several biotic features of interest, this property contains the habitat of an unusual salamander population, the crevice salamander, formerly known as *Plethodon longicrus*, but now considered a variant of *Plethodon yonahlossee*. Access to the property is being strictly controlled by the Conservancy. "No Trespassing" signs have been posted along the boundaries, and the property is being patrolled regularly. Use of the tract will be limited to scientific research and monitoring, and two organized field trips each spring and summer.

As part of the Stewardship Master Plan, a herpetofaunal inventory, with emphasis on *Plethodon yonahlossee* and *Aneides aeneus* will be conducted in 1981 by Richard C. Bruce and students from Western Carolina University. In addition, George Labanick of the University of South Carolina at Spartanburg is beginning long-term population studies of *Plethodon yonahlossee*.

Herpetologists should not attempt to enter the Bat Cave property without permission. Collecting will be discouraged. Individuals with legitimate scientific interests will be considered eligible for study permits, and should contact the N. C. Nature Conservancy, P.O. Box 805, Chapel Hill, North Carolina 27514. ●

ERRATUM

Podocnemis INFO SOUGHT

The Milwaukee County Zoo would appreciate receiving information on any captive breeding program (successful or not) for turtles of the Genus *Podocnemis*, especially *P. expansa*. Please send information to:

Reptile Section
Milwaukee County Zoo
10001 West Bluemound Road
Milwaukee, WI 53226 ●

NEW BOOK

INVENTORY OF LIVE REPTILES AND AMPHIBIANS IN NORTH AMERICAN COLLECTIONS, CURRENT JANUARY 1, 1981
by
Frank L. Slavens

This book contains approximately 200 pages of information compiled from 160 (70 public and 90 private) reptile and amphibian collections. Detailed information, such as the location and sex of all individual specimens of 1,244 forms of 927 species; a list of species bred during 1980; and miscellaneous breeding information (including dates of egg laying and hatching, types of incubation media used, and temperatures); is included. For more information, contact: Frank L. Slavens; P.O. Box 30744, Seattle, Washington 98103.

BOG TURTLE PRESERVE

Environmental Conservation Commissioner Robert F. Flacke today announced acquisition of key habitat lands in southeastern Putnam County, which will be known as the Bog Brook State Nature Preserve.

Almost 132 acres of land were acquired from several owners at a total cost of more than $500,000. The project was funded through the unique-area category of the 1972 Environmental Quality Bond Act.

"The Bog Brook Preserve was acquired primarily to protect its population of bog turtles, one of our endangered species," Commissioner Flacke explained. "This is the first time the state has purchased land to protect a species that is in danger of extinction."

Studies by DEC over the past three years show that 47 percent of previously known bog turtle habitats in the state can no longer support this species. The state Nature and Historical Preserve Trust, which controls expenditure of funds for the purchase of unique areas, had recommended the Bog Brook acquisition, following confirmation of its population of bog turtles and of the danger that this habitat would be destroyed by development. Dr. John Behler, a herpetologist with the New York Zoological Society, was instrumental in identifying the Bog Brook habitat, and provided much essential information to DEC prior to the acquisition. About 30 percent of the Bog Brook acreage is in wet meadows. The remaining land in the acquisition slopes upwards, and is a mixture of old fields and deciduous woodlands. The upland areas in the Preserve were purchased to protect the wetland's water supply. ●

THE DIVERSITY OF FEEDING MECHANISMS OF SNAKES

A Symposium
Supported by the Division of Vertebrate Morphology of the American Society of Zoologists

Dallas, Texas — 27 December 1981

Symposium Organizer: F. Harvey Pough, Section of Ecology & Systematics, Langmuir Laboratory, Cornell University, Ithaca, New York 14850

A Symposium Banquet and a Reception in the Reptile House of the Dallas Zoo are planned for the evening of 27 December.

Contributed papers about snakes will be scheduled for the following day, 28 December. ●

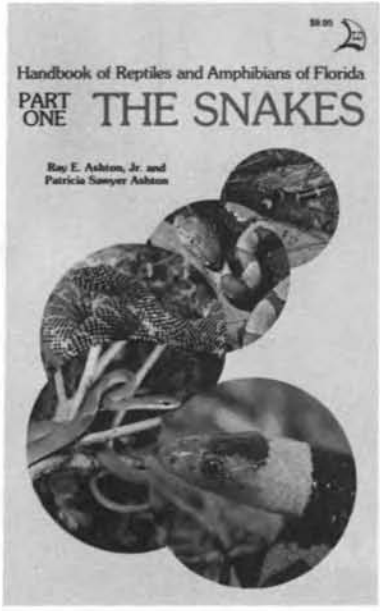
HR NEEDS HELP

Barbara Paschke will no longer be able to manage the myriad tasks associated with advertising in **HR.** As editor, I would like to express SSAR's sincerest appreciation, not to mention my own personal thanks, for her efforts these past several years. Her sincerity and energy in the task helped to advance the Society quite a bit financially; she is not a member, nor even a herpetologist.

I will be unable to absorb her workload. Hence, unless a capable volunteer steps forward for this task, revenue from ads in **HR** will take a tumble. Perhaps those few at August's Board meeting who clamored loudly for a **more active HR** ad program will now rush forward and demand to be the one to head the effort. Of course, as I recall, they did only say that **someone** should do it.

Anyway, we do need help. The work will require 2-5 hours a week, a fair amount of typing, excellent organizational ability, the ability to write personable as well as forceful letters, and an employer willing to pay modest postage costs (or the ability to launder said costs since there never was an advertising budget!).



I am poised now, prepared to review the untold numbers of applications. ●

Pythons & Boas

Authentic 9 X 11 reproductions of antique B&W illustrations of the Boidae, with emphasis on scalation and coloration patterns. Print no. 1, featuring the Ringed, Children's, Carpet, Green, Olive, Papuan, Di Albert's, Amethystine, and Reticulated Pythons, is now available for only $5.95 + $1.50 postage. Reptile Reproductions, 1210 Fairbanks Drive, Austin, TX 78752.

THE SNAKES

Beautiful Full Color Photographs

Complete Species Accounts

Range Charts

Detailed Drawings

Ray E. Ashton, Jr. and Patricia Sawyer Ashton
North Carolina State Museum of Natural History

The Snakes is part one of an ambitious three volume set of books comprising **The Handbook of Reptiles and Amphibians of Florida.** Magnificent color photographs, along with species accounts which include descriptions, habitats, similar species, natural history and range charts, identify all of the snakes found in Florida. Detailed drawings emphasize characteristics which aid in identifying the different snakes.

TWO ABNORMAL STRIPING PATTERNS IN *EUMECES LATICEPS*

Among hundreds of adult and juvenile *Eumeces laticeps* observed in Alabama between 1976 and 1979, two phenotypically aberrant individuals were noted. Both were recently hatched individuals on a study area being censused repeatedly in a mark-recapture survey. Each was returned to the population after marking and neither was seen again. Although they may have emigrated, it is more likely that they died on the site since one was notably weak when captured, since aberrant phenotypes often have exceptionally high death rates, and even normal hatchlings are subject to a high mortality rate.

The first unusual specimen appeared normal except that its middorsal light stripe was interrupted above the pectoral girdle by a yellow oval the perimeter of which was of the same width and color as the middorsal line (fig. 1). Since the oval was continuous with the middorsal stripe anteriorly and posteriorly, it appeared to be formed by a bilaterally symmetrical branching of the stripe with convergence of the branches on the midline at each end. The lizard bearing the elliptical marking was captured on 7/13/78, the first day hatchlings appeared on the study site that year. Its weight was 0.81 g and its snout-vent length 33 mm.

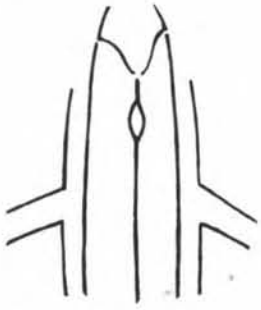

Fig. 1. Elliptical dorsonuchal striping anomaly.

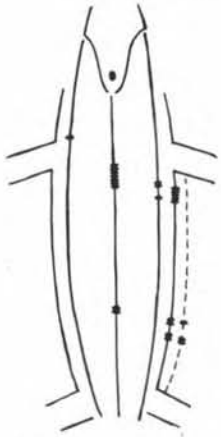

Fig. 2. Anteroposterior location of each blue scale on an otherwise yellow stripe is indicated by one dark line perpendicular to the stripe.

Although the stripes of the other specimen were normally aligned, there were numerous scales restricted to the stripes considerably anterior to the tail which were light blue rather than the normal yellow (fig. 2). Several photographs retained by the author document this phenomenon. Blue scales occurred in two oblique patches. In the anterior patch, just posterior to the pectoral girdle, one blue scale was located on the stripe just left of the middle stripe at the level of the pectoral girdle, seven blue scales were in the middorsal stripe just posterior to the pectoral girdle, four blue scales in three groups separated by yellow scales were a little further back on the stripe just to the right of the midline, and five consecutive blue scales were found at the same level on the next stripe. The posterior patch, located slightly anterior to the pelvic girdle, was restricted to the midline and the three stripes on the right side (*E. laticeps* often has seven). As in the anterior patch, the anterior-most blue scales were on the left-most affected stripe. The stripe just right of center lacked blue scales in the posterior patch, but proceeding to the right, the next stripe had two pairs of blue scales separated by three yellow ones, and the lateral stripe had one blue scale at the level of the anterior pair on the adjacent stripe and two blue scales at the level of the posterior pair.

Because the blue scales on the dorsal trunk occurred in patches and showed similar pigmentation to that normally found only on the tail and tail base, they probably indicate a genetically mosaic distribution of pigmentation.

The hatchling with anterior blue scales was captured on 8/2/79, four days after the first sighting of hatchlings on the study plot that year. Its size (36 mm snout-vent length and 0.77 g body weight) and absence of an open yolk scar suggest that it may have survived a week or more after hatching. However, it neither appeared nor acted vigorous. Besides its unusual stripe coloration, it had an abnormal kink in the last 15 mm of the tail.

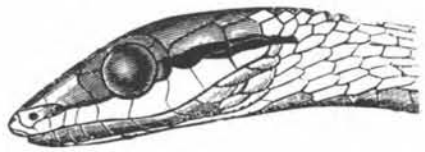
EXCAVATING BEHAVIOR IN *CONOPHIS LINEATUS* (SERPENTES: COLUBRIDAE)

An adult *Conophis lineatus* (*ca.* 45.0 cm SVL) collected near Managua, Nicaragua in February 1976 was housed in a glass enclosure 75 x 75 x 30 cm. The sides of the enclosure were covered with paper and observations were made through several small reclosable flaps. The enclosure included a water receptacle and several flat rocks on a pea gravel substrate. The rocks were of various sizes but all laid flush with the 1.5 - 2.0 cm - deep substrate. Late in the afternoon of the

day after being introduced into the enclosure the *Conophis* was observed excavating beneath one of the rocks. It would push its snout into the gravel beneath the rock, bend its head and neck into an acute angle around some of the gravel and then pull the gravel out from beneath the rock. This behavior was repeated until a cavity was formed beneath the rock. The snake then crawled into the cavity and assumed a coiled position with its head resting on a body coil.

The next morning, after the snake had left the cavity, we pushed pea gravel beneath the rock to once again make it flush with the substrate. Again, late in the afternoon, the snake excavated a cavity beneath the same rock and retreated into it. It then used that retreat for several days, until we again filled it in. Once again it was re-excavated. The snake fed readily on anoles and half-grown laboratory mice and frequently attacked them from its retreat.

Schmidt and Davis (1941:49) briefly discussed burrowing in snakes and noted that " . . . certain snakes have been seen to use a loop of the neck to scrape out small hollows in the sand . . . " but that " . . . no one knows why or how generally snakes use it." Williamson (1971) observed five species, representing five genera and three families (Boidae, Colubridae, Elapidae), to exhibit excavating similar to that described above for *Conophis lineatus.* He suggested that the behavior represented an attempt by the snakes to escape since the excavated areas were adjacent to the glass walls of their enclosures.



The behavior we observed in *C. lineatus* was obviously not an attempt to escape. The excavation took place under a rock centrally located in the enclosure and the snake was clearly making a retreat for itself. Whether the cavity merely represented a place to spend the night, a site from which to ambush prey, a retreat to return to when potential predators appeared, or a home base to be returned to repeatedly and which may have served various functions, is unknown.

HAVE YOU SEEN A BULLFROG-GREEN FROG HYBRID?

The bullfrog, *Rana catesbeiana*, and the green frog, *Rana clamitans*, are two of the most common and the most widely-distributed frogs in North America. They are so similar in appearance that green frogs and small bullfrogs are frequently mistaken for each other by the casual observer. Using a biochemical measure, Wallace *et al.* (1973) found that these two species are closely related. In addition, there are striking similarities in their mating behavior. In both, receptive females enter into a male's territory which he defends, and females may mate more than once in the summer (Wells, 1977; Howard, 1978). Because of these similarities, the question arises as to whether hybrids between them can be produced.

Previous work indicated that hybridization could not occur. In the cross, *R. catesbeiana* ♀ x *R. clamitans* ♂, the embryos arrested at gastrulation, and in the reciprocal cross, *R. clamitans* ♀ x *R. catesbeiana* ♂, no eggs were fertilized (Moore, 1955). I found that the block to fertilization of the *R. clamitans* egg was overcome by enrobing the egg with *R. pipiens* jelly (Elinson, 1975a) or simply by using much higher concentrations of *R. catesbeiana* sperm (Elinson, 1975b). Once the block to cross-fertilization was circumvented, the resulting embryos developed in a normal fashion through metamorphosis (Elinson, 1975a). Such froglets grew into healthy, mature hybrid adults, and one, in fact, overwintered in an outdoor pond.

When the hybrids reached sexual maturity, I examined them for fertility. Several males (Elinson, 1977) and one female tested (Elinson, unpublished) were fertile. By back-crossing these fertile hybrids to the parental species, I have been able to do a genetic analysis of lethality in the *R. catesbeiana* ♀ x *R. clamitans* ♂ cross. The failure of these embryos to gastrulate may be due to only one early acting gene (Elinson, 1977, unpublished). The conclusions from these experiments are that fertile hybrids between *R. clamitans* and *R. catesbeiana* can be produced and that the lack of development in one direction of the cross does not indicate a large genetic difference between the species.

Is the hybrid produced in nature? A scenario for this would be for a large *R. clamitans* ♀ to wander into the territory of a small but virile *R. catesbeiana* ♂ and be amplexed by him. Problems with this are: 1) Do small, mature *R. catesbeiana* males release enough sperm at amplexus to fertilize *R. clamitans* eggs? 2) Would a *R. clamitans* which has survived years of predation by *R. catesbeiana* approach a *R. catesbeiana*? 3) Are there behavioral cues which could preclude a successful amplexus?

Despite these problems, I would like to alert you to the possibility of finding a hybrid in nature. A mature adult hybrid can be distinguished from the parental types without undue difficulty. The hybrid is sexually mature when it is about 7 cm snout to vent, similar to *R. clamitans*. Sexually mature *R. catesbeiana* are generally greater than 10 cm. *R. clamitans* has distinct dorsolateral folds which *R. catesbeiana* lacks. The hybrid has faint or no folds. So a 7-9 cm sexually mature "green" frog with faint folds would be likely candidate for a hybrid (see Elinson 1977, for pictures). If you suspect that a frog is a hybrid, the hybrid can easily be distinguished from the parental species with a more detailed morphological analysis (Scheuler and Elinson, unpublished) or by an examination of the enzyme lactate dehydrogenase (Elinson, 1975a). I would, of course, be interested to hear of any suspected hybrids. Happy hunting!

SSAR PUBLICATIONS

FACSIMILE REPRINTS IN HERPETOLOGY

Initiated in 1961, this series serves to make rare and important books and papers on amphibians and reptiles available once again to persons working in the field. All reprints are exact photolithographic facsimiles; all are paperbound unless otherwise indicated.

•BELL, T. 1843. Herpetology of the "Beagle". Part V of Darwin's classic **The Zoology of the Voyage of the H.M.S. Beagle** contains descriptions of 46 species (25 being new) of amphibians and reptiles collected on that renown expedition. 100 pages, 20 plates, 8½ x 11 in.
Introduction by Roberto Donoso-Barros. paperbound $10.00 ☐ clothbound 15.00 ☐

•BOJANUS, L. H. 1819-1821. Anatome Testudinis Europaeae. The classic atlas of turtle anatomy, with an introduction by A. S. Romer. 200 pages (7 x 10 in.) plus 40 plates (10 x 14 in.). paperbound $25.00 ☐

•BOULENGER, G. A. 1877-1920. Contributions to American Herpetology. A series of collected papers from various journals; complete in 18 parts totaling about 900 pages. Illustrated. 6 x 9 in.
Introduction and Table of Contents. Parts 1-10, 1877-1897, plus personal comments on Boulenger by J. C. Battersby. $ 2.00 ☐

Part 1.	1877-1881. 6 papers. 32 p.	2.00 ☐
2	1882-1883. 12 papers. 48 p.	2.00 ☐
3	1884-1885. 10 papers. 44 p.	2.00 ☐
4	1886-1887. 10 papers. 56 p.	2.00 ☐
5	1888. 13 papers. 32 p.	2.00 ☐
6	1889-1890. 10 papers. 48 p.	2.00 ☐
7	1891-1893. 11 papers. 44 p.	2.00 ☐
8	1894. 5 papers. 40 p.	2.00 ☐
9	1895-1896. 11 papers. 52 p.	2.00 ☐
10	1897. 2 papers. 56 p.	2.00 ☐
Table of Contents. Parts 11-18, 1898-1920.		2.00 ☐
11	1898. 4 papers. 52 p.	2.00 ☐
12	1899-1900. 9 papers. 48 p.	2.00 ☐
13	1901-1902. 7 papers. 34 p.	2.00 ☐
14	1903-1904. 8 papers. 28 p.	2.00 ☐
15	1905-1911. 12 papers. 42 p.	2.00 ☐
16	1912-1913. 6 papers. 46 p.	2.00 ☐
17	1914-1919. 8 papers. 38 p.	2.00 ☐
18	1920. 3 papers. 64 p.	2.00 ☐
Index. 44 p.		2.00 ☐
Complete set, 18 pts. plus index.		$35.00 ☐

•BULLETIN OF THE ANTIVENIN INSTITUTE OF AMERICA. Volumes 1-5. 1927-1932. Complete set of an important journal devoted to the taxonomy, biology and distribution of snakes, lizards, salamanders and crocodilians. 575 pages, 163 photographs, maps, index. paperbound $25.00 ☐ clothbound 28.00 ☐

•CAMP, C. L. 1923. Classification of the Lizards. The foundation of modern lizard systematics; with a new preface by the author and an extensive review of current literature by Garth Underwood; plus index. Illustrated. 5½ x 8½ in. 220 pages. paperbound $20.00 ☐

•CHANG, M. L. Y. 1936. Amphibiens urodeles de la Chine. The standard work on Chinese salamanders with a new checklist by Arden Brame. Illus. 5½ x 8½ in.; 168 pages; 5 plates. paperbound $ 8.00 ☐

•COPE, E. D. 1864. Papers dealing with Anuran Taxonomy. Reprinted from The Proceedings of the Academy of Natural Sciences of Philadelphia and The Natural History Review. 20 pages. paperbound $2.00 ☐

•COPE, E. D. 1871. Catalogue of Batrachia and Reptilia obtained by McNiel in Nicaragua. Catalogue of Reptilia and Batrachia obtained by Maynard in Florida. 8 pages. $1.00 ☐

•COPE, E. D. 1892. The osteology of the Lacertilia. An important contribution to lizard anatomy, reprinted from the Proceedings of the American Philosophical Society. 42 pages, 6 plates. $2.00 ☐

•COWLES, R. B. and C. M. BOGERT. 1944. A preliminary study of the thermal requirements of desert reptiles. This influential paper is reprinted from AMNH Bulletin 83, article 5 plus an introductory essay by F. Harvey Pough. 34 pages, illustrated. $3.00 ☐

•D'ORBIGNY, A. 1847. Voyage dans l'Amerique meridionale. This extract comprises the complete section on reptiles and amphibians. All text and plates have been reproduced in their original size. 10 pages, 8½ x 11 in.; 9 plates. $3.00 ☐

•DUNN, E. R. 1926. Salamanders of the Family Plethodontidae. A recognized classic treatment of the plethodontid salamanders, including tropical and European species. A new introduction by David Wake and Arden Brame provides a modern appraisal of this work. Illus.; 6 x 9 in.; 472 pages; 3 plates; 86 maps; index.
paperbound $15.00 ☐ clothbound 20.00 ☐

•ESCHSCHOLTZ, F. 1829-1833. Zoologischer Atlas (herpetological sections). Descriptions of new reptiles and amphibians from California and the Pacific. 8½ x 11 in.; 32 pages. $2.00 ☐

•De La ESPADA, D. M. J. 1875. Vertebrados del Viaje al Pacifico. A reprint of the most famous of Espada's works in herpetology. An essential reference for anyone interested in the amphibians of South America. With an introduction and biography by J. M. Savage. 208 pages; 6 plates. clothbound $15.00 ☐

•FITZINGER, L. J. 1843. Systema Reptilium. An important nomenclatural landmark for herpetology, including amphibia as well as reptiles; world-wide in scope. 6 x 9 in.; 128 pages; portrait.
Introduction by Robert Mertens. paperbound $11.00 ☐ clothbound 15.00 ☐

•GLOYD, H. K. 1940. The Rattlesnakes, Genera Sistrurus and Crotalus. A study in zoogeography and evolution. Introduction by H. M. Smith and H. S. Harris. Jr. 300 pages plus 31 plates of photographs. Index. 7 x 10 inches. clothbound $20.00 ☐

•GRAY, J. E. 1825. A synopsis of the genera of reptiles and Amphibia. 32 pages. paperbound $2.00 ☐

•GRAY, J. E. 1831-1844. Zoological Miscellany. A privately printed journal, devoted mostly to descriptions of amphibians, reptiles and birds from all over the world. This reprint comprises the entire series and includes a new introduction and biography of Gray by Arnold Kluge. Illus.; 5½ x 8½ in.; 86 pages; 4 plates.
paperbound $ 6.00 ☐ clothbound 10.00 ☐

•HOLBROOK, J. E. 1842. North American Herpetology. Five volumes bound in one. This is an exact facsimile of the second edition, including all 147 plates, 19 reproduced in full color. An introduction, a biography by Dr. and Mrs. Worthington and a new portrait of Holbrook by David Dennis are added. 1000 pages; 8½ x 11 inches.
clothbound $60.00 ☐

•JUNIOR SOCIETY OF NATURAL SCIENCES (CINCINNATI, OHIO). 1930-1932. Herpetological papers from the Society's Proceedings, with articles by Weller, Walker, Dury and others. 56 p.
paperbound $2.00 ☐

•KIRTLAND, J. P. 1838. Zoology of Ohio (herpetological portion). 8 pages. paperbound $1.00 ☐

•LeCONTE, J. E. 1824-1828. Three papers on amphibians from the Annals of the Lyceum of Natural History, New York. 16 pages.
paperbound $1.00 ☐

•LINNAEUS, C. 1766-1771. Systema Naturae (ed. 12) and Mantissa Plantarum (herpetological portions from both). 56 pages.
paperbound $2.50 ☐

•LOVERIDGE, A. 1946. Reptiles (and Amphibians) of the Pacific. The standard reference to the herpetofauna of the region extending from Indonesia to Hawaii and the Galapagos. 271 pages, 7 plates, 1 double-page map. 8 x 5½ in. paperbound $15.00 ☐

•McILHENNY, E. A. 1935. The Alligator's Life History. The most complete record of the natural history of the American alligator with a new preface by Archie Carr. 125 pages, 18 photographs and a portrait. 9 x 6 in. paperbound $15.00 ☐ clothbound 18.00 ☐

•McLAIN, R. B. 1899. Contributions to North American Herpetology. Three privately printed papers containing important distributional records and the description of a new form. 26 pages.
Index. paperbound $1.00 ☐

•RAFINESQUE, C. S. 1820. Annals of Nature (herpetological and ichthyological sections). 4 pages. $0.50 ☐
_____. 1822. On two new salamanders of Kentucky. 2 pages. $0.50 ☐
_____. 1832-1833. Five herpetological papers from the Atlantic Journal. 4 pages. $0.50 ☐

•VON SPIX, J. B. and J. G. WAGLER. 1824-1825. Herpetology of Brazil. The most comprehensive and important early survey of the herpetology of Brazil. Includes tables of species names with modern equivalents. Introduction by Professor Vanzolini with the itinerary of the expedition, a review of type localities and a historical discussion of the expedition. This book is an important reference for those interested in South American herpetology. 400 pages. (98 plates).
clothbound 36.00 ☐

•TROSCHEL, F. H. 1850 (1852). Cophosaurus texanus, neue Eidechsengattung aus Texas. 8 pages. $1.00 ☐

•TSCHUDI, J. J. von. 1838. Classification der Batrachier. A major work in systematic herpetology, with a new introduction by Robert Mertens. 118 pages, 7 x 10 in.; 6 plates. paperbound $10.00 ☐
_____. 1845. Reptilium conspectus. Descriptions of new reptiles and amphibians from Peru. 24 pages. paperboard $1.00 ☐

•VAN DENBURGH, J. 1895-1896. Herpetology of Lower California. A review of the herpetology of lower California (collected papers). 96 pages, 11 plates. paperbound $ 4.00 ☐

•WILLISTON, S. W. 1925. Osteology of the Reptiles. A reprint of a classic which has long been out-of-print. It includes a new preface by C. W. Hibbard. Illus.; 6 x 9 in.; 304 pages. paperbound 10.00 ☐ clothbound 14.00 ☐

•WRIGHT, A. H. and A. A. WRIGHT. 1962. Handbook of Snakes of the United States and Canada. Vol. III Bibliography. Out of print since about 1969 this bibliography is a necessary companion to Volumes I and II. clothbound $15.00 ☐

Journal of Herpetology,

official scientific journal of the SSAR. It is international in its scope and is open to original research articles on amphibians and reptiles, including notes, regular papers and reviews. Illustrated. 7 x 10 inches; title-pages and indices are included gratis with complete volumes.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

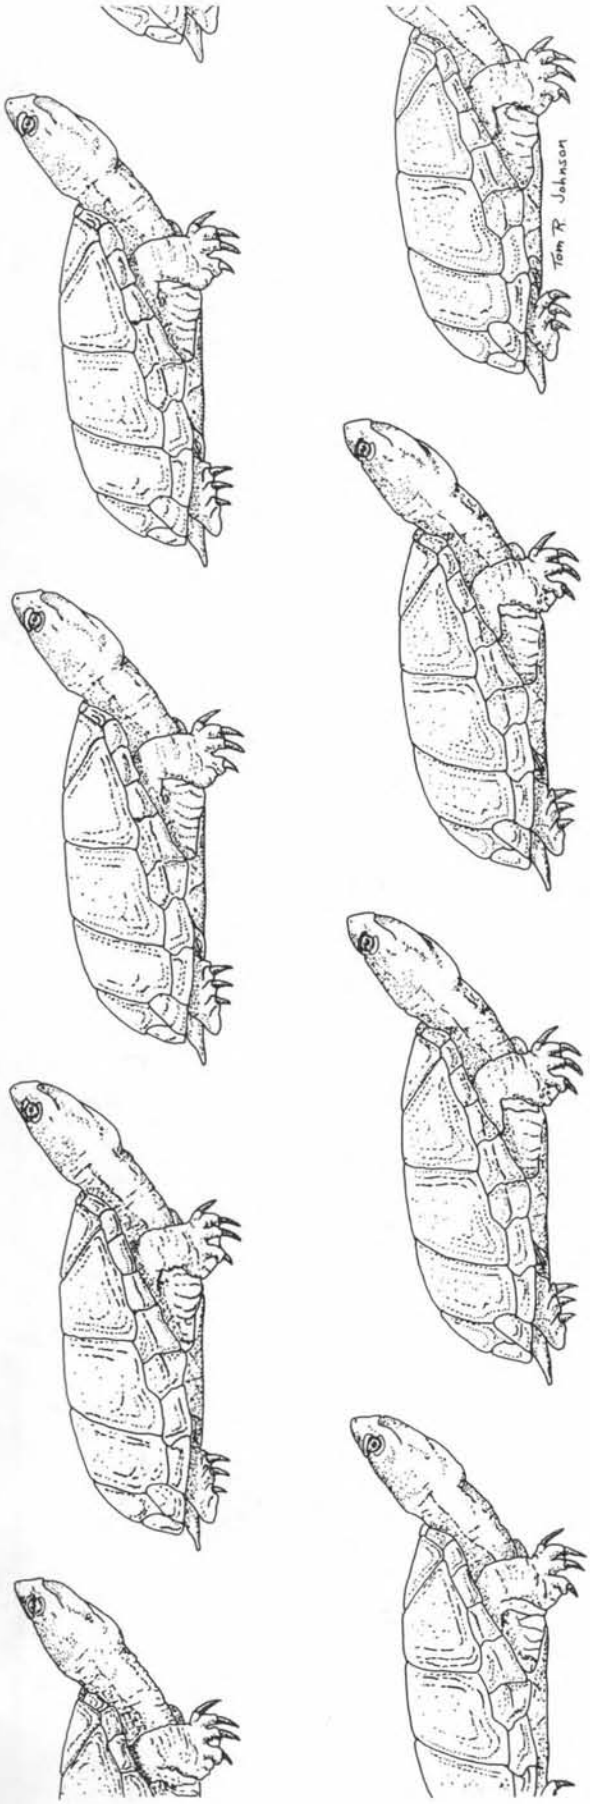
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), **Herpetological Circulars**, and several **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES

(Please send only U.S. funds; make checks payable to SSAR)



Student member	$15.00
Regular member	$18.00
Sustaining member	$25.00
Contributing member	$30.00
Institutional	$30.00

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR 25th ANNIVERSARY MEETING

The dates for the 1982 Annual Meeting in Raleigh, North Carolina are August 1-6. Further details will be announced in December. ●

ATTENTION ALL CURRENT LITERATURE SCANNERS

To update the records of assignments for active CL scanners, it will be greatly appreciated if **all** scanners will submit a complete list of journals/sources each is currently responsible for to the new CL Coordinator, Joe Dinardo, as soon as possible. Please send this information to:

Joe Dinardo
Current Literature
16 Idlewild Road
Levittown, PA 19057 USA

It has become apparent that there is some duplication of effort taking place, while a number of other journals/sources are being neglected. These seem to have been dropped by previous scanners and not reassigned. In an effort to correct these deficiencies, the cooperation of everyone presently scanning for CL will be most appreciated. Only with this information at hand can the situation be rectified. ●

APPEAL TO ALL MUSEUM WORKERS AND LIBRARIANS

During the last several years, it appears that notification of many herpetological titles issued in the various publications series of natural history museums have escaped the attention of **HR's** Current Literature section. This is true not only of overseas institutions, but, oddly enough, of many North American museums and scientific societies as well.

Since many of these publications constitute important herpetological reference materials, this deficiency needs to be corrected. In an endeavor to get as many such publications listed in CL as possible, it will be greatly appreciated if any museum workers or librarians who have knowledge of such titles will bring them to the attention of Joe Dinardo, the Current Literature Coordinator, at the following address:

Joe Dinardo
Current Literature
16 Idlewild Road
Levittown, PA 19057 USA

In addition, in order to fill the gaps in the reporting of this information that has occurred in the past, it will be most useful if a list of all such titles published in the last five to ten years by your facility be supplied as well. Please include the following information for each title submitted: author(s), date of publication, title in full, publication source, volume and/or number and exact pagination.

The assistance and cooperation of all librarians and museum workers who supply this information will be most appreciated by the editors of Herp Review and its readership at large. ●

HERP CATALOGUE ACCOUNTS OPEN

CROCODYLIA

Volunteers are sought for three crocodilian accounts for the Catalogue of American Amphibians and Reptiles. The account for *Crocodylus acutus* and the generic accounts for *Alligator* and *Crocodylus* are still unassigned. Anyone wishing to volunteer for either of the accounts please contact:

HOWARD W. CAMPBELL
Crocodylia Editor
National Fish and Wildlife Laboratory
Gainesville Station
412 N.E. 16th Avenue, Room 250
Gainesville, FL 32601 ●

SERPENTES

I have been fortunate during my tenure as the Snake Section Editor for the Catalogue of American Amphibians and Reptiles in having the support of many colleagues who have volunteered to author most of the U.S. snake accounts. There are a few accounts, however, that remain unassigned. I want to take this opportunity to bring to your attention a list of these accounts in the hope that some of you may be interested in volunteering to write one or more of these accounts or that you might be able to suggest someone you think might be interested and/or qualified to write one or more. The list of unassigned U.S. snake accounts is as follows:

1. *Coniophanes*
2. *Masticophis lateralis*
3. *Nerodia cyclopion*
4. *N. erythrogaster*
5. *N. fasciata*
6. *N. harteri*
7. *N. rhombifera*
8. *N. sipedon*
9. *N. taxispilota*
10. *N. valida*
11. *Rhadinaea*
12. *Thamnophis radix*

I am also interested in hearing from people who would like to volunteer to write accounts of exotic snake species from elsewhere in the Western Hemisphere.

If you can help, please contact me at:

NATURAL HISTORY PRINTS
BY DAVID M. DENNIS

WE ARE PLEASED TO ANNOUNCE that wildlife prints by David Dennis are available for sale. These portraits are *full-color reproductions* of the original watercolor drawings, each printed on a sturdy paper stock measuring 20 by 24 inches and suitable for framing. Prints are *strictly limited to an edition of 500 copies, each of which the artist has numbered and signed individually.* Because of the relatively small size of the edition and the fact that this is the first offering of Mr. Dennis' work, these prints represent a sound investment as well as a visual delight. They would also be ideal for gifts.

Mr. Dennis is widely known to the scientific community as a wildlife artist specializing in watercolor portraits of lower vertebrates and insects. His self-taught artistry is complemented by his academic training in biology and his personal field experience with each of the animals he paints. Mr. Dennis earned his undergraduate degree in zoology from The Ohio State University in 1966 and since then he has held a succession of positions as biological illustrator at the Columbus Zoological Gardens, the University of Kansas Museum of Natural History and now at Ohio State. He has illustrated numerous biology textbooks including one which he co-authored, but is perhaps best known to vertebrate biologists for the exquisite series of watercolors published in *Hylid Frogs of Middle America* (The University of Kansas Press, 1970). Originals of Mr. Dennis' watercolors have been exhibited in art galleries and museums throughout the United States and also at numerous scientific meetings.

TO ORDER please use the form provided below:

_____
your name (please print)

_____
address *city* *state* *zip*

Please mark the appropriate boxes and fill in the last column.

☐ Plate 1: *Green Frog*, $25 each	$.
☐ Plate 2: *Painted Turtle*, $25 each	.
☐ Plate 3: *Spotted Salamanders*, $25 each	.
☐ Plate 4: *Hercules Beetle and Red Salamander*, $25 each	.
☐ Plates 1-4: *Set of all 4 plates* (if ordered together), $85	.

Make your check payable to BIOGRAPHICS. Prints are packed with care and shipped pre-paid and insured world-wide. Allow 4 weeks for delivery, longer overseas.

New York State residents, please add 7% sales tax	+ .
Packing, postage, insurance	+ 4.50
TOTAL REMITTANCE	$.

REGIONAL SOCIETIES

Manuscripts on the biology of amphibians and reptiles are wanted for publication by the Chicago Herpetological Society. The CHS publishes a BULLETIN 4 times per year and material for 1981 issues is needed. Black and white photos of amphibians and reptiles are also needed. Please submit material to the: Publication Secretary, Chicago Herpetological Society, 2001 North Clark Street, Chicago, IL 60614. ●

THE VIRGINIA HERPETOLOGICAL SOCIETY IS RESTRUCTURED

In March of 1981 the VaHS held a meeting at Longwood College in Farmville, Va.

The purpose of the meeting was to restructure the society after a two year lapse of formal meetings.

The Board of Directors was replaced by an elected body of officers. The officers are:

President - Bob Bader
Vice-President - Jack Brooks
Secretary - Joseph C. Mitchell
Editor - Don Merkle

A new bulletin will be published this summer before a Sept. 1981 meeting. After the meeting if there is enough interest the bulletin, which is called CATESBEIANA, will be published semi-annually.

Although the main interest of the VaHS is still the herpetology of the state, we will not limit ourselves to just state wide herp information.

Anyone wishing to receive the bulletin this summer please contact Don Merkle at Longwood College, Biology Dept., Farmville, Va. 23901. ●

Bipes IN ALTA CALIFORNIA

The recent exchanges in *Herpetological Review* regarding the presence of *Bipes* in the United States (Campbell, 1980; Gans and Pappenfus, 1980; Dundee, 1980 and Smith and Holland, 1981) reminded us of an overlooked report of *Bipes* in Central California. The report was one of more than a dozen historical accounts given orally in 1877 by Jose Francisco Palomares, an early pioneer in California, and recorded by the historian Thomas Savage (Temple, 1955). The manuscript containing the remembrances was deposited in the Bancroft Library, University of California, Berkeley, and a translation by Temple was published in 1955. Since this report is not in the herpetological literature and otherwise not readily available in most libraries, we have taken the liberty of quoting it as it was published in the *Memoirs of Jose Francisco Palomares* (Temple, 1955:33-36):[1]

"Curious case of an Indian who died as the result of an ajolote.

"Once we were hunting deer in company with Don Ygnacio Ortega, a man well versed in matters of the hunt and of a very harsh character. One night while we were resting in camp, located at La Poza del Fresno (the pool of the fresno), after having skinned the deer that we had killed during the day, we noticed that there crawled out of the water a great number of little animals resembling [salamanquesas], ravenously consumed the blood that had collected there. We paid little attention to such vermin and everyone retired without any misgivings.

"Some of us slept and others rested, when there were heard some hearty shrieks from the Indian Ygnacio, servant of Ortega, yelling, 'Ouch! Ouch! the snake, he crawl in! Ouch! Ouch! the snake he crawl in!' Immediately, we were all moving around and snatching some live fire brands went to see what was happening to Ygnacio, whom we found squatting down with his hand clenched under his anus, from which there writhed the tail of an animal, which we at once recognized as an ajolote . . . 'This snake hurts very much, Señor! With his claws he is tearing me,' replied the Indian.

"Then Ortega went to where the patient was lying and said to him, 'Let me grab it and I'll pull it out.' The Indian answered, 'But don't let him get in any further, Señor, no! here, I have hold it.' The Indian released his hand and Don Ygnacio yanked, but the animal would not budge, perhaps because it was hooked on to the insides by its small sharp claws . . . Then Ortega, with the faggot in hand, burned the Indian about the thighs, pulling at the same time on the tail of the ajolote. The patient let out a scream of pain and Ortega yanked out the animal and flung it away from there.

"The anus of the Indian looked on the outside like a rosette, and then we saw that he had jagged wounds from which the blood flowed freely. For all that we did we could not stanch the flow. Ortega, grumbling and swearing, ordered us to break camp, but not before some of us went to where the ajolote lay and killed it. Examining it we found that on [las dos patitas que tenia por delante], very similar to human hands, you could see some short, little claws, steel-like and as sharp as needles. Then we realized that those little knives must have horribly wounded the insides of the hapless Ygnacio . . . Finally, after twenty-four hours of bleeding from his wounds, José Ygnacio expired at La Panocha Chiquita; the body was brought to the Mission of San Juan Bautista, where he belonged, and there he was given Christian burial."

There can be little doubt that the ajolote described by Sr. Palomares was a *Bipes*. His description of the animal (a snake with sharp claws on its two small human-hand-like paws) is a reasonably accurate one for *Bipes*. Ajolote is the common name applied to *Bipes biporus* of Baja California. Furthermore, the description of the behavior of the ajolote is similar to the behavior attributed to *Bipes* in the La Paz area; however, there it more commonly involves women rather than men. Although it would not be unreasonable to question the veracity of some aspects of the circumstances of the encounter with the ajolote, it remains an intriguing possibility that they actually found and killed a *Bipes* in Central California.

The hunt related probably took place in the 1820's. Sr. Palomares was born in 1806 and his hunting companion, Don Ygnacio Ortega, died in 1829. The location of the hunt was somewhere near Little Panoche Creek (La Panocha Chiquita) in the Panoche Hills in what is now western Fresno or adjacent San Benito County, California. The Poza del Fresno could have been what is now called Mercy Hot Springs. This area lies in the western edge of the San Joaquin Valley. The habitat consists of rolling sandy hills dominated by annual grassland with a mixture of shrubs (*Atriplex polycarpa, Ephedra californica* and *Haploppus racemosus*) (Barbour and Major 1977:495), and is well suited for a burrowing animal like *Bipes*. The area is sparsely populated and remains, from a herpetological standpoint, one of the least explored in California.

Does *Bipes* await rediscovery in Central California?

[1]Bracketed sections are in the original Spanish from the manuscript in the Bancroft Library.

BOOK REVIEWS

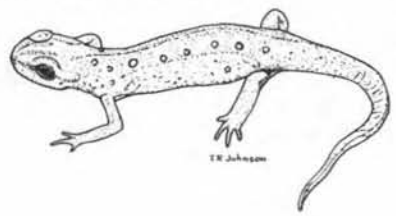
J. D. Romer, **Illustrated Guide to the Venomous Snakes of Hong Kong** H.K. Government Press: Hong Kong.

The most popular of the Hong Kong Urban Services Publications, this small colorful booklet was originally published in 1959. An unexpected demand by tourists, teachers and students, and the general public resulted in a revised edition (1965), additional impressions (1966, 1972) and the present updated impression (1975).

Mr. Romer, who has served many years as Senior Pest Control Officer for Hong Kong, has been in an excellent position to survey the venomous snake fauna of the colony. In addition to responsibilities for insect and rodent control, his office responds to calls on snakes. Many-banded kraits entwined in telephone cables and Chinese cobras in Kowloon housing estates are not uncommon events.

Additionally, Mr. Romer has published numerous articles on both reptiles and amphibians, including an annotated checklist and key to the snakes of Hong Kong in 1970. However, only this guide to venomous snakes is still in print.

Eight snakes are pictured: *Bungaris fasciatus, B. multicinctus, Callophis macclellandi, Naja naja, N. hannah, Trimeresurus albolabris, T. monticola,* and *Hydrophis cyanocinctus.* An excellent chart detailing the features of dead venomous snakes constitutes the centerfold and neatly divides the booklet in half. The first twelve pages complete the narration in English. The last twelve pages are a repetition in Chinese and read from what westerners would consider to be the back cover. The pictures and center chart are illustrated but once and are captioned in both languages. This bilingual format is rather unusual and is a refreshing acknowledgment that the colony is mostly Chinese. It also accounts for the booklets exceptional popularity.



Page-long narratives on the description, occurrence and venom of each snake compliment the color plates. Recommendations for first aid for snake bite reflect the small size of the colony and the ready supply of antivenom.

The whole booklet is printed on heavy slick paper and stapled as one signature. Copies used as class manuals have admirably taken several years' wear. While it will not provide technical data new to the professional herpetologist, it is an excellent model of an educational booklet for a local scene.

(Copies currently sell for under U.S. $2.00 from the Hong Kong Government Printer, General Post Office Building, Central, Hong Kong. Surface mail should cost less than U.S. $.50, airmail not more than U.S. $2.00.)

SOUTH AFRICAN FROGS

N.I. Passmore & V.C. Carruthers

"This book will guide the newcomer gently into the specialized world of frogs, and show him beauty he would never expect. It will also guide him to the work still to be done — work to which the keen amateur can contribute." — Professor Hugh Paterson, Head of the Department of Zoology, University of the Witwatersrand, Johannesburg.

An authoritative guide to the diverse frog fauna of South Africa. Written and illustrated at a level of proficiency that will make it a standard reference work for herpetologists, ecologists, teachers, conservators and anyone with an interest in natural history. Profusely illustrated with photographs of living animals. A twin-page description for every species includes at least one colour photograph, several black and white photographs, a distribution map and in most cases a sonogram of the mating call. An annotated gramophone record of the calls of the majority of the species is included. 1979. 288 pp., 136 coloured plates, over 500 black and white photographs, drawings and distribution maps, 1 record of frog calls. Cloth R22.

Kluger, M. J. 1979. **Fever. Its Biology, Evolution, and Function.** Princeton Univ. Press. xxi + 195 pp, 49 figs. $15.00.

I doubt that many herpetologists will be induced to examine a book with such a clinical title as this one. Nonetheless if you can be intrigued by the thought of a lizard or a fish having a fever, you might be just the person to find this little exposition on the subject of fevers to be quite fascinating. The discovery that ectotherms (including reptiles and amphibia) do indeed possess febrile reactions to various pyrogens has reinforced the belief that any organic event with such a widespread evolutionary background must have an adaptive value and that the re-setting of the thermostat at an elevated temperature is a beneficial thermoregulatory response by the organism. As a logical conclusion to these discoveries, the clinical approach to fever (not to be confused with hyperthermia) should be to maintain it rather than to abate it with antipyretic drugs. It is demonstrated that the principal difference between ectotherms and endotherms lies in the effector arm of the thermoregulatory reflex arc rather than the sensory or integrating segments which are basically similar in all vertebrates. Once again we have a demonstration how laboratory experimentation with reptiles and amphibians can have a beneficial bearing on human welfare.

NEW BOOK

REPTILES OF THE SOLOMON ISLANDS by Michael McCoy. WAU ECOLOGY INSTITUTE Handbook No. 7, 1981. 80 pages; 8 color plates; 12 half-tone plates. Price: Kina 3.00, Sol. 4.00, US $5.00.

This handbook treats all of the reptiles known from the Solomon Islands (including Bougainville I. which is part of the nation of Papua New Guinea). Seventy-two species are described with information on distribution, characteristics, color in life, ecology and life-cycle. There are keys to all categories. Many of the species are illustrated both in color and half-tone. In addition, there are diagrams to assist in the use of the keys and descriptions. There is a glossary, a bibliography, instructions for preserving specimens and an index.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1978. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

CAUDATA

DESMOGNATHUS MONTICOLA (Seal Salamander). **COLORATION.** The only heretofore known literature record of a completely albino *Desmognathus* is apparently that of *D. monticola* from North Carolina reported by Brame (1962, Abh. und Berichte fur Naturk. Vorgesch. 11(3):65-81). During a collecting trip for the Kentucky Nature Preserves Commission (KNPC), a completely albino male *D. monticola* was collected from the Lower Pigeon branch of Elkhorn Creek, 2.6 km east of Hylton, Pike County, Kentucky on 13 Oct 1978. The specimen was taken along with 28 normally colored individuals including 2 *D. fuscus*, 3 *D. welteri*, and 23 *D. monticola*. Identification of the albino was confirmed by the use of toe pad characteristics and tooth morphology (Caldwell and Trauth, 1979, J. Herp. 13(4):491-497. The collection site was a small 2 m high steep-walled seepage area that had a small but continuous flow over layered moss-covered sandstone. A small overhanging ledge capped the wall. The east-facing area was littered with numerous leaves from the surrounding beech-hemlock-rhododendron forest.

The specimen measured 60 mm snout-vent length and had 13 costal grooves (3 intercostal spaces between adpressed limbs). Epidermal pigment was entirely lacking; the animal appeared completely white in normal daylight and possessed pink eyes. Underlying blood vessels were readily visible over the entire body. The tip of the tail had been lost and was being regenerated at the time of capture.

Following collection, the specimen was preserved in 10% formalin, then transferred to 70% isopropyl alcohol and is currently stored in the KNPC collection at Frankfort, Kentucky. The abdominal cavity was subsequently opened and examined. The only evidence of internal pigmentation was that of the blood. No food material was found in the stomach or intestine. Multiple testicular lobes were present and were scored as 2.5 on the right and 2.0 on the left according to Tilley (1973, Ecology 54(1):3-17). Lobe measurements in mm were as follows (posterior-most lobes recorded first): right = 3.0, 4.0, 4.0; left = 5.0, 3.5. The vasa deferentia were well developed and wavy in appearance. Based upon methods of assessing testicular characteristics (Humphrey, 1922, Biol. Bull. 43:47-67), the age of the albino was estimated at between 4 and 5 years.

Submitted by **WAYNE C. HOUTCOOPER,** Field Representative, Kentucky Nature Preserves Commission, 407 Broadway, Frankfort, Kentucky 40601

NECTURUS MACULOSUS LOUISIANENSIS (Red River Mudpuppy). **COLORATION.** Albinos of the subspecies *N. m. louisianensis* have not previously been reported. An albino *N. m. louisianensis* was collected on 9 March 1980 by Mr. Bill Todd, a local fisherman, from the Cache River near Egypt in Craighead County, Arkansas (T14N, R1E, Sec. 12). The mudpuppy is an adult (215 mm SVL). The specimen was donated to the Department of Biological Sciences, Arkansas State University, and was maintained in an aquarium for several months.

The specimen (Figure 1) has pink eyes. Its ground color is yellowish white with blotches of faint yellow in contrast to the lighter ground color. The yellow coloration is probably due to concentrations of lipophores, melanophores being absent. The ground color of the dorsum fades into a more translucent white on the venter, allowing portions of the circulatory and darker viscera to be seen. The circulatory system causes a pink cast to develop on the venter.

Fig. 1. Dorsal view of albino *Necturus maculosus louisianensis* from Craighead County, Arkansas.

The authors thank Mr. Bill Todd for donating the specimen, and Dr. Jeffrey H. Black, Oklahoma Baptist University, for providing technical materials. The specimen is now preserved in the Arkansas State University Herpetological Museum (ASUHM #3940).

Submitted by **CHRIS T. MCALLISTER,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203 and **C. RENN TUMLISON** and **LYNITA M. COOKSEY,** Department of Biological Sciences, Arkansas State University, P.O. Box MM, State University, Arkansas 72467

PLETHODON CINEREUS (Redback Salamander). **COLORATION.** During investigations on the ecology of *P. cinereus* at Victory Woods (1.7 km W Put-In-Bay), South Bass Island, 131 unstriped and 1 striped *P. cinereus* were collected. The striped morph (SV 25mm) was found with several unstriped morphs under a decaying log in typical woodland habitat for *P. cinereus* (Heatwole, 1962). This specimen, being the first record for the striped morph from the monomorphic unstriped South Bass Island population, was released at the capture site after being photographed.

The nearest *P. cinereus* populations in northern Ohio have greater percentages of striped morphs (7-80% striped; Pfingsten and Walker, 1978) and are now separated from South Bass Island by at least 4 km of water. Twelve thousand five hundred years ago though, the bottom of Lake Erie was virtually dry and was covered with forests (Forsyth, 1973, Compass Sigma Gamma Epsilon 51:16-26). During this period, South Bass Island could have been populated by salamanders following the retreating glacier. The subsequent reflooding of the western basin (3,500 to 4,000 years ago) would have isolated South Bass Island with its *P. cinereus* population (*ibid.*). The progression toward a monomorphic unstriped condition in this isolated population could then have occurred simply by genetic drift. Hence this lone striped *P. cinereus* may represent a relict gene in the population.

The field work would not have been possible without the help of T. Bonace, R. Carter, M. Duffy, D. Michael, and P. Zock. Dr. G. Dalrymple constructively criticized the manuscript.

Submitted by **NORMAN G. REICHENBACH,** Department of Zoology and The Center for Lake Erie Area Research, The Ohio State University, Columbus, Ohio 43210. ●

ANURA

BUFO PUNCTATUS (Red-spotted Toad). **LARVAL COLORATION.** There has been no record of an albino *Bufo punctatus*. On 25 August 1979, six albino Red-spotted toad tadpoles *(Bufo punctatus)* were found in No Thoroughfare Canyon, Colorado National Monument, just west of Grand Junction, Colorado. The canyon is arid, rocky, and divided by a small stream which is intermittently dry. Five of the albino tadpoles were found in one small pond. The other albino was in a separate pond 13 m downstream.

The site in No Thoroughfare Canyon was visited weekly between 25 August and 1 November 1979. A single albino tadpole was last seen on 7 October. Albinistic adults were not found during the study period. No albino toads or tadpoles have been discovered in the area since.

Submitted by **LAWRENCE K. LUEPSCHEN,** 837 Belford Ave., Grand Junction, Colorado 81501. ●

RANA CLAMITANS (Green Frog). **COLORATION.** An aberrant female Green frog, *Rana clamitans*, captured among a group of normally colored individuals on 13 July 1968 at Allenton Marsh, T11N, R18E, Sec. 35, Washington Co., Wisconsin, resembled a "melanoid" variant of *R. pipiens* described by Richards *et. al.* (1969, Copeia (4):850-852).

Color of live frog — Dorsum ground color was light tan to grayish-brown with heavy pigmentation from nape to vent producing a dusky appearance. The head and snout had small pigmented patches connected by short dark lines giving a net-like pattern. Laterally, dark coloration was confined to the proximity of the lateral folds. The legs had dark bar-like markings over a light grayish-brown ground color. Some areas beneath the rear legs had a dusky translucent appearance. The ventrum had a translucent appearance. Viscera were visible through the abdominal covering as darkened areas immediately caudal to the front legs. The iris of the eyes were totally black, lacking the normal gold flecked coloration.

Measurements (mm): S-V 60; head width 21; interocular distance 3.5; internasal distance 5; nostril-eye 4.5; snout-tympanum 15.3; eye-tympanum 1.3; tympanic diameter 7; eye diameter 8.

After preservation in 10% formalin and maintenance at 45° to 70° F for one year, the color pattern was compared to the living specimen using color notes and photographs. The dorsum was light gray and the dark areas were not altered by preservation. The light tan coloring disappeared, revealing 25 small spots on the dorsum above the vent. The widely spaced dark pigmented cells on the translucent ventrum were conspicuous after preservation. Two types of pigmented cell aggregations were observed on the ventrum. The first were very small (ca. 0.025 mm) and rounded, lying in the outer layer of the skin. The second were larger (ca. 0.076 mm) and more oval than rounded, and were located below the first group.

I thank Dr. Max Allen Nickerson for reviewing this manuscript. The preserved specimen has been deposited in the vertebrate collection at the Milwaukee Public Museum (18200).

Submitted by **RICHARD H. RADAJ,** 24130 W. Loomis Rd., Hales Corners, WI 53130. ●

SERPENTES

CEMOPHORA COCCINEA COPEI (Northern Scarlet Snake). **REPRODUCTION.** Relatively little is known of this species' distribution or life history in New Jersey. Therefore, the following new locality and reproductive data are of note.

On 1 July 1974, a gravid female *C. c. copei* (total length = 66.5 cm) was collected at Lake Oswego, Burlington County, New Jersey. The specimen was crossing an asphalt road at 2335 hr on a warm, damp evening with banks of low fog rising to about 76 cm above substrate. The week prior to collection was marked by heavy, intermittent rain.

The female was typical of the subspecies (Williams and Wilson, 1967, Tulane Stud. Zool. 13(4):103-124). On 7 July 1974, the female deposited eight white elongate eggs in a water bowl lined with moist sphagnum moss that had been placed in the specimen's enclosure for that purpose. The eggs adhered together in a single mass and ranged from 2.6-3.0 cm in length ($\bar{x}$=27.5cm) and 1.3-1.5 cm in width ($\bar{x}$=1.4 cm). These dimensions compare favorably with those of a clutch of eggs from North Carolina reported by Palmer and Tregembo (1970, Herpetologica 26:300-302).

The eggs were incubated in a plastic 20x15x10 cm refrigerator dish with multiple 4 mm holes drilled in the sides and top. The eggs were artificially incubated in moist sphagnum moss. Room temperature was approximately 24-25° C. Artificial heat was not used during incubation. All eight eggs hatched on 23 September 1974, seventy-eight days after deposition.

The young were similar in appearance to the adult. They were 16.5-18.5 cm in total length ($\bar{x}$=17.6 cm), and weighed 2.1-2.8 g in weight ($\bar{x}$=2.5 g).

Submitted by **ROBERT L. BRANDNER,** Department of Herpetology, New York Zoological Society, Bronx Zoo, Bronx, New York 10460. ●

CROTALUS LEPIDUS LEPIDUS (Mottled Rock Rattlesnake). **COLORATION.** Tryon (1979, Herp. Rev. 10(1):45) reviewed the many accounts of color and pattern deviations in snakes, and more recently Irwin (1979, Herp. Rev. 10(3):85) reported an aberrantly patterned *Crotalus viridus viridis* and *Sistrurus catenatus tergeminus*. In September or October, 1975, a male *C. l. lepidus* was collected 38.6 km north of Comstock in Val Verde Co., Texas. The body of the specimen is light gray and patternless dorsally, and cream-colored ventrally (Fig. 1). Small flecks of gray pigment occur randomly on the ventral scales. Its tail is cream-colored, except that the distal 1/3 of the ventral surface is rust-colored. Scale counts fall within the range for *C. l. lepidus*. Snout-vent length in November 1979 was 56.4 cm, and the animal appears to have grown little since collection.

The specimen is currently being maintained alive at the Houston Zoological Gardens, Texas (E-268). Upon death it will be placed in

Fig. 1. Patternless *Crotalus lepidus lepidus.*

the Texas Cooperative Wildlife Collection, Texas A & M University.

LAMPROPELTIS GETULUS CALIFORNIAE (California Kingsnake). **COLORATION.** On 13 March 1980, an unusual *Lampropeltis getulus californiae* was collected in northern San Diego County, California, by a resident collector. I obtained the specimen on 22 March and am presently maintaining it alive. Unfortunately, size was not recorded when the animal was collected. As of 22 July 1980, the snake weighed 14.1 g, and was 31.5 cm in length.

Both ventrally and laterally, the specimen is completely unpigmented, with the exception of a few flecks of yellow on the most anterior scutes, and normal pigmentation of the dorso-lateral head region. Because these unpigmented areas are quite translucent, most of the major internal organs can be clearly discerned through the body wall. The heart contractions can be seen, and consumed food items can be followed visually down the esophagus.

Dorsally, a light brown vertebral stripe, approximately 8-9 scale rows wide at the mid-body, runs the length of the specimen. This is broken by 36 irregularly shaped yellow crossbands, most at oblique angles to this dorsal stripe. Each of the crossbands averages 2-3 scale rows wide. The vertebral stripe appears to be only lightly pigmented, and is somewhat washed-out along the edges. Under magnification, many of the dorsal scales can be seen to be only marginally or apically pigmented.

The specimen appears to be normally pigmented on the dorsal medial head surfaces. The parietals are predominantly dark brown, with a few yellow spots. The frontals and supraoculars are dark brown posteriorly and yellow anteriorly. The prefrontals are completely yellow, with a suffusion of brown pigment along the margins. The internasals are medially margined with brown pigment, become yellow in the center of each scale, and are unpigmented along the distal margins. The nasals are completely unpigmented, except along the posterior margins where they are yellow. The rostral is yellow. The margins of both the upper and lower labials are unpigmented, with a few of the scales containing a central light suffusion of yellow pigment. The dorsal brown pigments darken as they descend from the vertebral stripe in the cervical region of the snake to a point just below (ventral to) the jaw axia.

The specimen presently appears to be in good health, and is feeding on newly born laboratory mice (approximately 1-2 g) 3 times per week.

When this snake reaches sexual maturity, selective captive breeding experiments are planned to determine the genetic nature of the phenomenon. The author solicits information on any similar specimens.

Submitted by **VINCENT N. SCHEIDT,** 6218 Syracuse Lane, San Diego, CA 92122. ●

LAMPROPELTIS G. HOLBROOKI (Speckled Kingsnake). **REPRODUCTION.** A gravid female speckled kingsnake *(Lampropeltis g. holbrooki)* was collected in Mohawk Park, Tulsa County, Tulsa, Oklahoma on 15 May 1979. The snake measured 63.0 cm SVL, 72.8 cm TL and weighed 159.5 g. It was found on the bank of a small creek bordered by willows and sedges at 1104 h. Air temperature was 27.5° C and substrate temperature was 27.0° C.

The snake was retained for observation. Ecdysis occurred on 8 June 1979 and 9 eggs were deposited in a box containing dampened paper towels on 20 June 1979.

Mean dimensions of the eggs were 32.0 mm (range = 29.0 - 36.5 mm) X 20.0 mm (range = 19.0 - 20.5 mm). Carpenter (1958, Herpetologica 14(2):113-115) recorded average egg dimensions of 29.8 mm X 20.3 mm from a female measuring 94.1 cm SVL and 105.3 cm TL. Mean dimensions of 16 eggs recorded by Force (1930, Copeia (2):25-39) were 36.7 mm X 19.2 mm.

One egg weighed 8.3 g. The remaining eggs were adherent and were not weighed. The eggs were incubated in a closed container of dampened vermiculite (Tryon, 1975, Bull. N. Y. Herp. Soc. 11:33-37) at 24 - 32° C.

The snake weighed 93.5 g following egg deposition. After consuming a dead mouse on 22 June, it was scale clipped as part of a herpetological survey of the area and released at the capture site on 26 June.

Hatching began on 9 August and all young had emerged by 10 August, an incubation period of 51 days. Anderson (1965, The Repts. of Mo.) noted an incubation period of 64-67 days and Gloyd (1928, Trans. Kans. Acad. Sci. 31:115-141) stated eggs laid on 22 June pipped 24 August, a 63 day incubation period. The young were measured via the squeeze-box technique. Mean SVL was 20.5 cm (range = 19.6 - 21.7 cm), mean TL was 24.1 cm (range = 23.2 - 25.2 cm), and mean weight was 6.3 g (range = 5.6 - 7.0 g). All young were released on 12 August at the female's capture site.

Submitted by **RUSSELL D. GRIMPE** and **GERALD E. BENEFIELD,** Department of Herpetology, Tulsa Zoological Park, 5701 E. 36th N., Tulsa, Oklahoma 74115. ●

OPHEODRYS V. VERNALIS (Smooth Green Snake). **REPRODUCTION.** A female (brown color phase) captured 2 July 1968 (gravid condition not noted while captive) laid 12 eggs under a plastic tile. The eggs were removed 5 August. Portions of the eggs were wrinkled and flattened, indicating an earlier laying date. Wright and Wright (1957, Handbook of Snakes of the US and Canada) report an egg laying period for this species from 24 June to 15 September. Incubation was in a sealed plastic bag containing a layer of damp aquarium gravel and maintained at 19° - 22° C in subdued natural light. The eggs regained a normal shape the following day. Egg slitting began on 24 August (Table 1). Wright and Wright *(ibid.)* quoted Blanchard, "The interval from laying to hatching varied on the cases under observation from 4 to 23 days." Table 2 shows the total length of hatchlings. These lengths fall into the species' normal range.

Table 1. Egg Slitting Sequence (day of August 1968/no. hatched/hours). Four eggs failed to hatch.

24/1/1800	27/1/0730
25/1/0900	27/1/1800
25/1/1330	28/1/1900
26/2/0730	

Table 2. Hatchling Size (mm).

Number of Hatchlings	Total Length	Tail Length
1	114.3	25.4
5	127.0	31.8
1	120.7	38.1
*1	95.3	28.5

* Backbone deformed in 5 places.

Often, the hatchlings would not leave the egg after slitting the shell. Instead, they would project only their head and a small part of their body, sometimes retreating into the protective egg. One individual took two days to completely leave the egg. Upon complete emergence, the hatchlings would construct a depression along the plastic wall, below the surface of the gravel.

The hatchlings' dorsal color was slate-gray to brown with a bronze sheen, and their abdominal surface was white. The typical green coloring began to develop on 5 September, and by 1 November, four hatchlings transformed to the light green coloring while four hatchlings retained the grayish-brown coloration. The young began accepting small field crickets and red worms on 8 September.

I thank Dr. Max Allen Nickerson for reviewing this manuscript. The four brown color phase hatchlings have been deposited in the vertebrate collection at the Milwaukee Public Museum (18201 thru 18204).

Society for the Study of Amphibians and Reptiles

BALLOT

This is the official ballot of the SSAR to elect officers for 1982. All SSAR members are urged to vote and return this ballot no later than 1 October 1981 in the enclosed self-addressed envelope.

For President-elect (vote for one):

- ☐ Ralph W. Axtell
- ☐ Thomas A. Jenssen

For Secretary (unopposed):

- ☐ Joseph T. Collins
- ☐ _____

For Treasurer (unopposed):

- ☐ Henri C. Seibert
- ☐ _____

For Board of Directors (Class of 1984 — vote for two):

- ☐ Robin Andrews
- ☐ Thomas H. Fritts
- ☐ Norman J. Scott
- ☐ Craig Weatherby

Information about each candidate is provided on the reverse of this ballot.

In compliance with the requirements of the SSAR constitution, the following amendment to the SSAR By-laws was approved by the SSAR Board of Directors, published in Herpetological Review 12(1): 3, presented during the general business meeting of the SSAR at Memphis, and is here presented for a vote by the entire SSAR membership.

Shall Article VII, section 2 of the SSAR By-laws be amended to read:

"The amount of dues shall be established by the Board of Directors."

☐ Yes ☐ No

Return this ballot to:

DAVID G. BARKER

The Candidates

RALPH AXTELL, Professsor of Biological Sciences, Southern Illinois University, Edwardsville; PhD, University of Texas, Austin; Research interests: systematics, zoogeography and evolution of amphibians and reptiles (especially iguanid lizards); SSAR activities: Acting Board director for annual meeting, reviewer for Grants-in-Herpetology program, reviewer for **Journal of Herpetology;** Publications: 35 research publications plus reviews, essays, maps and paintings.

ROBIN ANDREWS, Assistant Professor, Department of Biology, Virginia Polytechnic Institute and State University, Blacksburg; PhD, University of Kansas, Lawrence (1971); Research interests: ecological energetics of reptiles; SSAR activities: member of Kennedy Award Committee; Publications: *ca.* 20 publications on the ecology of tropical lizards.

JOSEPH T. COLLINS, Vertebrate Zoologist, Museum of Natural History, University of Kansas, Lawrence; Research interests: natural history of North American amphibians and reptiles; SSAR activities: President (1978), Secretary (1962-1971; 1980 to date), Editor Herp Review (1967-1969), Co-editor Herp Review (1977-1979), numerous committees, etc.; Publications: *ca.* 90 publications (including 4 books).

THOMAS H. FRITTS, Wildlife Biologist, U.S. Fish and Wildlife Service, Tulane University Museum of Natural History, Belle Chasse, Louisiana; PhD, University of Kansas (1972); Research interests: evolution and ecology of reptiles and amphibians, especially in southern U.S., Latin America, and in arid and montane temperate and tropical regions, plus special research interests in marine turtles, land tortoises and iguanid evolution; SSAR activities: member of Kennedy Award Committee; Publications: 29 publications in herpetology and related fields.

THOMAS A. JENSSEN, Associate Professor of Zoology, Virginia Polytechnic Institute and State University, Blacksburg; PhD, University of Oklahoma; Research interests: behavioral ecology and animal communication of amphibians and lizards; SSAR activities: member of **Journal** editorial board; Publications: 28 papers and chapters in 3 books.

NORMAN J. SCOTT, JR., Zoologist, U.S. Fish and Wildlife Service, and Adjunct Associate Professor, Department of Biology, University of New Mexico, Albuquerque; PhD, University of Southern California (1969); Research interests: biogeography of reptiles and amphibians of northwestern Mexico, and distribution and systematics of the herpetofauna of Paraguay; SSAR activities: SSAR symposium organizer (1977); Publications: 14 publications (9 of which are on reptiles and amphibians).

HENRI C. SEIBERT, Professor of Zoology, Ohio University, Athens; PhD, University of Illinois, Urbana (1947); SSAR activities: Treasurer (1970 to date), Publications Secretary (1966-1976), Board of Directors (1962 to date); Publications: dozens.

CRAIG WEATHERBY, Assistant Professor of Biology, Adrian College, Adrian, Michigan; PhD pending, Auburn University, Alabama; Research interests: ecology, ethology and evolution, with particular emphasis on endangered species and population genetics.

THREE ALBINO SNAKES from Nicaragua: An Update. Villa & Rivas (1972, Rev. Biol. Tropical 19:159-163) reported on 3 albino snakes from Nicaragua: *Boa constrictor imperator* Daudin (Boidae), *Leptodeira annulata rhombifera* Günther (Colubridae) and *Crotalus durissus durissus* Linnaeus (Crotalidae). At that time two of the snakes were living and the third was preserved in a museum. Changes in the status of all these snakes, and frequent inquiries on their whereabouts, prompts this note.

Boa constrictor imperator. — This snake was owned by Gustavo Villanueva, who obtained it near Juigalpa (Departmento de Chontales, Nicaragua) in 1970. Repeated attempts were made to purchase or borrow the snake for breeding purposes but he did not oblige. He had promised to deposit it, once dead and preserved, in the Museo de Juigalpa. The last time I saw the albino boa it had nearly doubled in size to about 2 m. Since then, in 1980 it escaped from its cage and was killed by neighbors. Because of differences Villanueva had with the Museo de Juigalpa, the snake was neither preserved nor donated. Instead, he buried it in an undisclosed site, and it is therefore no longer available.

Crotalus durissus durissus. — I obtained a preserved albinistic specimen of this rattlesnake (Fig. 1) from an unknown locality in Nicaragua, and deposited it in the Museo Nacional de Nicaragua in 1960. The museum was largely destroyed by an earthquake in December 1972. Although some materials were salvaged from the museum, much was looted and destroyed. None of the alcoholic specimens were recovered; thus, the white rattlesnake is also no longer available.

Leptodeira annulata rhombifera. — An albino individual of this form was collected near Rivas (Departamento de Rivas, Nicaragua) by Amado Jiménez in 1970. The snake died in 1972 after regurgitating 3 small, recently eaten leptodactylid frogs. It is now preserved in the herpetological collection, Museum of Natural History, The University of Kansas (KU 187897).

SAURIA

***XENOSAURUS GRANDIS.* FOOD.** Published information regarding the diet of *Xenosaurus grandis* is restricted to King and Thompson (1968, Bull. Fla. St. Mus. 12(2):93-123). Discussion of food studies occupy a single paragraph which states "No food studies have been made on these lizards. Presumably they feed on soft-bodied invertebrates . . . ."

Examination of x-rays of specimens *Xenosaurus grandis* from Cuautlapan, Vera Cruz, Mexico (USNM series 111525-27) revealed the presence, in a female specimen, USNM 111525, of a second vertebral column, a portion of tail vertebrae, and complete hindlimbs and forelimbs of a prey item. Removal of the stomach contents revealed an undigested lizard minus head and distal portion of the tail.

Identification of the remains clearly indicated the genus *Sceloporus.* Without a complete specimen, and therefore lacking several key characters, a tentative identification of *Sceloporus formosus* Wiegmann was obtained. Identification was based on Smith and Taylor (1950, U.S.N.M. Bull. 199). This species of *Sceloporus* is known to occur in the vicinity.

The taking of lizards as a food item is quite common in many lizards, (*e.g., Tupinambis* and *Callopistes,* Family Teiidae; in *Gerrhonotus,* Family Anguidae; *Varanus,* Family Varanidae; *Crotaphytus,* Family Iguanidae). All of these species are known to take a variety of food items ranging from small soft-bodied arthropods to small mammals and birds.

Submitted by **WILLIAM PRESCH,** Department of Biological Sciences, California State University, Fullerton, California 92634. ●

TESTUDINES

CHELONIA MYDAS MYDAS (Green Turtle). **NESTING.** There are no known nesting records for this species in Georgia. To date, the northernmost published record for nesting in *C. m. mydas* is 16 km north of the Volusia County line, Florida (Stoneburner et al., 1979, Herp. Rev. 10(3):103-104). The nesting reported herein occurred approximately 242 km north of that record.

A female *Chelonia m. mydas* was observed nesting on Jekyll Island, Glynn County, Georgia on 27 June 1979 at 0335 hours. The crawl extended approximately 82 meters from the water to the spring tide line, and the nest was constructed 2.5 meters above that on a small incline in an advancing dune area, where 115 eggs were deposited. Unlike loggerhead sea turtles *(Caretta caretta),* this green turtle held both rear flippers together over the nest cavity during oviposition. The turtle measured 96.5 cm straight-line carapace length; straight-line carapace width was 76.5 cm. The turtle was untagged, and bore no tag scars. We placed two plastic tags on the front flippers: GA0235 (left, blue Jumbo Rototag) and GA0628 (right, yellow Riese tag). Although the beach was patrolled nightly until 15 August, reemergence by this individual was not observed.

The eggs were placed in the loggerhead hatchery on the island, which was unfortunately destroyed by Hurricane David. The eggs were salvaged and opened after the storm, and 92.2% (106 of 115) were fertile. Preserved embryos and photographs of the female on the nest document this report.

Submitted by **SALOME C. LITWIN,** Department of Zoology, University of Rhode Island, Kingston, R.I. 02881. ●

CHRYSEMYS CONCINNA TEXANA (Texas River Cooter). **MORPHOLOGY.** On 15 April 1978, a dicephalic *Chrysemys concinna texana* was collected in Mesquite City Lake Park, Dallas County, Texas. The collector was J. Hemby who later gave the turtle to James Murphy at the Dallas Zoo. When the turtle died, Murphy preserved it and placed it in the University of Kansas Collection (KU 180253).

The turtle was normal in all other respects. The turtle was a juvenile, estimated to be about two months old, with a shell length of 30.2 mm. Width was impossible to determine because of the condition of the specimen. It died from causes unknown. Both heads appeared fully functional.

I wish to thank Joseph T. Collins and William Duellman for allowing me to examine the specimen. Also, I wish to thank James Knight for help with the measurements and for providing additional information.

Submitted by **JIM PILCH, JR.** 808 West 27th Street, Lawrence, Kansas 66044. ●

GOPHERUS AGASSIZI (Desert Tortoise). **LONGEVITY.** Reported longevity records for the desert tortoise, *Gopherus agassizi* range from 2+ yrs. (Conant & Hudson, 1949, Herpetologica 5:1-8) to 30+ yrs. (Patterson & Brattstrom, 1972, Herpetologica 28:169-171). All records are from captive specimens or tagged individuals, as it is impossible to age tortoises by reading growth rings (Miller, 1955). The following record indicates that the desert tortoise has a longer life span than previously reported.

David L. Jennings (in a letter to the author), reports he was given a male desert tortoise in the fall of 1928 from a group of three individuals collected by neighbors from the Mojave Desert near Victorville, San Bernardino County, California during the summer of the same year. This tortoise has been in continuous possession of the Jennings family for the past 52 years.

According to Mr. Jennings, the tortoise was approximately " . . . as long as a legal sized envelope . . . " (23 cm) at the time of receipt. Photographs of the specimen from the early 1930's confirm this. Thus, with an approximate carapace length of 23 cm, the tortoise was presumably an adult when it was brought

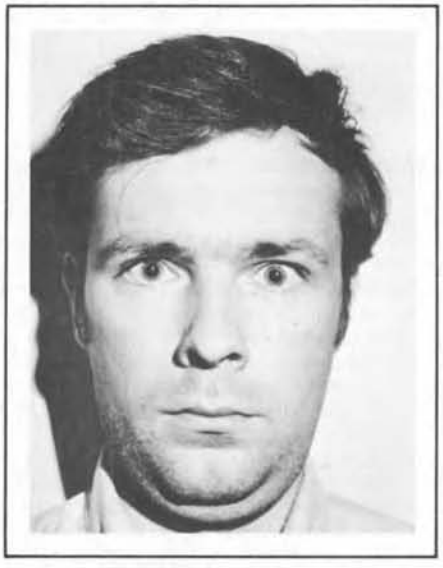
into captivity and is likely an additional 15 to 20 years older than its known 52 years (Patterson and Brattstrom, *ibid.*).

The tortoise's measurements as of May 18, 1980 are as follows: plastron length, 34.2 cm; carapace length, 29.4 cm; greatest carapace width, 24.8 cm; shell height, 12.5 cm; weight, 5.67 kg. The specimen was still alive at the time this paper was submitted (November 20, 1980).

My thanks to David L. Jennings, Roy F. Jennings, and Helen V. Sowers Jennings for their contributions to this manuscript.

Submitted by **MARK R. JENNINGS,** Department of Fisheries, School of Natural Resources, Humboldt State University, Arcata, California 95521, USA. Present Address: 605 Ellfred Court, Santa Paula, CA 93060. ●

TRIONYX SPINIFERUS (Spiny Softshell). **MORPHOLOGY.** A clutch of 12 eggs of *Trionyx spiniferus* was partially exposed by storm erosion two meters from the water line and 2/3 meters above the water line on 22 June 1980 in the Fobb Bottom area of the Red River arm of Lake Texoma, Marshall County, Oklahoma.



These eggs were collected and incubated in a screen cylinder under sand in the open. The eggs were checked weekly. When observed on 20 July, one egg appeared slightly cracked and was removed to check the progress of development. Fortuitously, when opened, this egg contained twin embryos (see illustration). Both embryos showed movements of the front legs and eyelids and appeared to be near hatching. None of the other eggs contained two embryos. The twin embryos were bathed with physiological salt solution and were still alive when preserved three days later.

WANTED

SLIDES of HERPETOLOGISTS

I AM PREPARING A MULTI-SCREEN SLIDE SHOW ENTITLED "HERPETOLOGISTS THEN AND NOW", WHICH WILL BE PRESENTED DURING THE 25TH ANNIVERSARY MEETING IN RALEIGH.

YOUR HELP IS VITAL TO THE PRODUCTION OF A GOOD SHOW. I NEED SLIDES OF AS MANY HERPETOLOGISTS AS POSSIBLE. IF YOU HAVE FUNNY OR EMBARRASSING SLIDES (NO PORNO PLEASE!) SEND THEM TO DAVID DENNIS, DEPARTMENT OF BOTANY, THE OHIO STATE UNIVERSITY, 1060 CARMACK ROAD, COLUMBUS, OHIO 43210.

YOUR SLIDES WILL BE HANDLED WITH EXTREME CARE, AND RETURNED PROMPTLY AFTER THOSE CHOSEN FOR THE SHOW HAVE BEEN DUPLICATED.

REMEMBER, YOUR FRIENDS WILL BE SENDING SLIDES OF YOU!

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

TESTUDINES

CHELONIA MYDAS AGASSIZI (Pacific Green Turtle). USA: ALASKA: *ca.* 1 November 1976. Eliza Harbor, Admiralty Island (Lat. 57.16 N., Long. 134.15 W.). Dead on beach at mean high tide level; head, body and limbs intact; apparent predation on neck by terrestrial mammal (mink?); estimated shell length 76 cm.; carcass discarded (Ken Gilpin, Petersburg, Alaska, pers. comm.). Skull (Figure 1) in

private collection of Ken Gilpin with eventual deposition in herpetological collections, Tongass Historical Society Museum, Ketchikan, Alaska. Skull examined and identified by author on 2 July 1981. The log of the Petersburg, Alaska fishing vessel TETA contains the following information: 9 October 1976, 9:30 a.m., Pt. Macartney, Kuprenoff Island, air temperature 8-10 Degrees C., slight ripple at surface, overcast, turtle alongside boat, basking at surface, as boat approached within 1.5 m. turtle submerged and surfaced approximately 9 m. from boat then disappeared, swimming actively, estimate shell length 76 cm. (Dale Bosworth, Petersburg, Alaska, pers. comm.). The Bosworth sighting apparently is the same turtle as the Gilpin specimen. Pt. Macartney is approximately 9 km. due southeast of Eliza Harbor. When shown unidentified illustrations/photographs of all sea turtles by author on 2 July 1981 Gilpin and Bosworth independently identified turtle as *Chelonia mydas.* In the northeastern Pacific Ocean, *Chelonia mydas agassizi* has been

recorded from Ucluelet, British Columbia (48.15 N. Lat.) and Eliza Harbor, Alaska (57.16 N. Lat.) which is the northernmost Pacific Ocean record to date (Hodge, 1976, Amphibians and reptiles in Alaska, the Yukon and Northwest Territories, Alaska Northwest Publishing Company, Anchorage). *Chelonia mydas agassizi* is the second species of turtle recorded from Alaska wasters. *Dermochelys coriacea schlegeli* has previously been reported (Hodge, R. P. 1979. Geographic Distribution: *Dermochelys coriacea schlegeli*. SSAR Herp. Review 10(3):102). The *Dermochelys* sightings occurred in August and September, the *Chelonia* sighting in October.

Submitted by **ROBERT PARKER HODGE,** Tongass Historical Society Museum, 629 Dock Street, Ketchikan, Alaska 99901. ●

SAURIA

CNEMIDOPHORUS GULARIS (Texas Spotted Whiptail). USA: TEXAS: Young Co: 8 km NE of Eliasville on FM 701 at Brazo's River-Clear Fork bridge. 5 June 1981. C. T. McAllister. Verified by J. R. Glidewell. North Texas State University Herpetological Collection (NTSUHC #R-701). New county record and partly fills distributional gap of tri-county area in extreme northcentral Texas (Raun and Gehlbach, 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2). Several other specimens were collected and released. Intensive collecting efforts for *C. gularis* may reveal populations for adjacent distributional hiatus in Baylor, Jack and Clay Counties, Texas.

Submitted by **CHRIS T. MCALLISTER AND MICHAEL C. WOOTEN,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink) USA: ARKANSAS: Ashley Co: 0.6 km S of Crossett on AR 133, T19S, R8W, S23. 14 May 1976. C. R. Tumlison. Verified by E. J. Bacon and V. R. McDaniel. Private collection of C. R. Tumlison (#50); Drew Co: 16 km N of Monticello on AR 81, T11S, R8W. 6 April 1969. D. Walls, and T13S, R8W, S18. 3 May 1969. V. Ward. Verified by E. J. Bacon. UAM Collection of Vertebrates (UAM 341-342); Union Co: 3.2 km E of Strong on AR 82, T18S, R12W, S26. 22 April 1978. C. R. Tumlison. Verified by E. J. Bacon. UAM Collection of Vertebrates (UAM 1414).

Additional records indicate that the species is more widely distributed throughout southeastern Arkansas, but is uncommon in many localities (Dellinger, S. C. and J. D. Black. 1938. Occ. Pap. U. Ark. Mus. (1):1-47. Dowling, H. G. 1957. Occ. Pap. U. Ark. Mus. 3:1-51; Conant, R. 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston. SERPENTES

COLUBER CONSTRICTOR FOXI (Blue Racer). USA: MICHIGAN: Benzie Co: 12.1 km. N. Bear Lake on US 31, 2.4 km. N. border Manistee County. 3 September 1978. J. W. Fitzpatrick. Identified by A. Resetar. Field Museum of Natural History (FMNH 207692). This is the first record of the occurrence of *Coluber constrictor foxi* in Benzie County. This species occurs in Manistee County which forms the southern boundary of Benzie County (Pentecost and Vogt, 1976. Environmental Status of the Lake Michigan Region. Volume 16. Amphibians and Reptiles of the Lake Michigan Drainage Basin). This DOR specimen was found about 1000 hours 30 m. from beech-maple forest edge among open, old cherry plantations and young pines in old field.

Submitted by **ALAN RESETAR,** Division of Amphibians and Reptiles, Field Museum of Natural History, Roosevelt Road at Lake Shore Drive, Chicago, Illinois 60605. ●

ELAPHE GUTTATA GUTTATA (Corn Snake). USA: KENTUCKY: Hardin Co: Killed in a garden on Lee School Road, 4 km SE White Mille. 26 May 1981 by Mrs. Floyd Booker. Verified by R. E. THAMNOPHIS SIRTALIS PALLIDULA (Maritime Garter Snake). CANADA: QUEBEC PROVINCE: Bonaventure Co: (Gaspé Peninsula) Port Daniel Reserve. Elev. 30 m. 48° 15' N, 64° 59' W. 7 August 1961. National Museum of Canada (NMC 6725). In grass on banks of the Rivière Port Daniel. Verified by F. R. Cook, National Museum of Canada.

Submitted by **NORRIS S. DENMAN,** 350 William Burks St., St. Bruno, Quebec, Canada, J3V 1P2. ●

NEW DEPARTMENTAL RECORDS OF *Liolaemus wiegmannii* FROM URUGUAY

The iguanid lizard *Liolaemus wiegmannii* (Duméril and Bibron, 1837) is known to occur on the southern Uruguayan coast at the Departamentos de Canelones (Devincenzi, 1926), San José, Maldonado (Vaz-Ferreira and Soriano, 1960), and Rocha (Lema and Fabián-Beurmann, 1977). A recent study on its ecology has shown that this lizard occupies the southern sandy coastal biotope, so the absence of literature records from the remaining coastal Departamentos was an enigma. Revision of material at the Dpt. Zoologia-Vertebrados, Facultad de Humanidades y Ciencias (ZVC-R) and Museo Nacional de Historia Natural (MNHN) provided the following new departmental records:

DPT. RÍO NEGRO: Río Negro, in front Villa Soriano. 18-23 December 1968. C. S. Carbonell and F. Achaval. ZVC-R 774; DPT. SORIANO: Mouth Río San Salvador. 12 August 1956. G. Debores. MNHN 154; DPT. COLONIA: Santa Aana, Artilleros. 6 February 1958. R. Larrosa. MNHN 165. Nueva Palmira. 10 January 1973. Marta Leprati. ZVC-R 1967 to 1969. 3 km E Martín Chico. 11 November 1973. A. Langguth. ZVC-R 2164. Balneario Brisas del Plata. 30 March 1975. A. Langguth. ZVC-R 2105. Cerro San Francisco. 22 February to 2 March 1974. V. Bonino. ZVC-R 2109; DPT. MONTEVIDEO: Alrededores de Montevideo. No date. R. Escalante. MNHN 142. Malvín. 1939. No collector. MNHN 163. Malvín. 30 April 1965. E. García and S. Klappenbach. MNHN 1064. Malvín. February 1965. S. Klappenbach. MNHN 1065. Parque Rivera. 11 December 1964. S. Klappenbach. MNHN 1079.

Thus, the distribution is now documented to the South Río Uruguay, Río de la Plata and Atlantic Ocean coasts. This lizard is continuously distributed over about 750 km of sandy coasts in southern Uruguay. All specimens were verified by Federico Achaval, who is acknowledged for his permission to examine the material under his care (ZVC-R and MNHN).

DISTRIBUTIONAL STATUS OF AN INTRODUCED LIZARD IN FLORIDA: *Anolis sagrei*

Since the early record of *Anolis sagrei* from Key West, Monroe County, Florida by Garman (1887), the range of this introduced

lizard in Florida has been reported to include: Hillsborough County, Tampa; Pinellas County, St. Petersburg; Palm Beach County, Lake Worth (Oliver, 1950); Dade County, Miami (Bell, 1953); metropolitan Broward, Dade, Monroe and Palm Beach Counties (King, 1960; King and Krakauer, 1966) Collier County, Chokoloskee Island (Conant, 1975); Glades County, Palmdale, Fisheating Creek Camp Ground (Corwin *et al.*, 1977); St. Johns County, St. Augustine (Maylan, 1977); St. Lucie County, Ft. Pierce (Myers, 1978); Lee County, Sanibel Island; Levy County, Waccasassa Marina (Funk and Moll, 1979). Herein, we report 29 additional localities for *A. sagrei* in Florida, including nine new county records, and comment on its present distributional status within the state. Unless otherwise indicated, all localities represent established (breeding) populations for which voucher specimens (collected and verified by J. S. Godley) are available at the University of South Florida, Tampa. Successful breeding was inferred from large population size and/or multiple size class representation at a site.

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Collier Co: Monroe Station, 14.2 and 21.2 km S US 41 on SR 94 (Loop Road). 24 April 1976. JSG 5343-44. Common on limestone rocks and shrubs bordering SR 94; only *A. carolinensis* seen in adjacent hammock and wet prairie habitats. Collier Co: Naples, US 41. 12 September 1977. Common within city limits; no voucher specimens taken. Dade Co: Everglades National Park, Anhinga Trail Visitors Center and Pa-Hay-Okee Overlook. 24 April 1976. No voucher specimens taken within Park. Common in shrubs and on boardwalk at Anhinga Trail Visitors Center. At Pa-Hay-Okee Overlook only one subadult male seen on boardwalk; may not be established at this site. Dade Co: 3.8 km SE Goulds (R40E, T56S, Section 21). January-July 1979. J. Rossi. Verified by J. S. Godley. Dade Co: 12.9 km ENE Homestead (R40E, T56S, Section 5). January-July 1979. J. Rossi. Verified by J. S. Godley. Dade Co: 5.3 km SE Florida City (R39E, T58S, Sections 3 and 4). January-July 1979. J. Rossi. Verified by J. S. Godley. The last three localities are the first records of *A. sagrei* from non-edificarian habitats in southern Florida. All specimens (N=95) were taken by J. Rossi in drift fence pit-fall traps set in Brazilian pepper *(Schinus terebinthifolius)* or Australian pine *(Casuarina equisetifolia)* habitats. Traps were set 0.32 km to 2.89 km ($\bar{x}$=1.48 km) from the nearest paved road. Highlands Co: Lake Placid, jct US 27 and SR 17, Lewis' Truck Stop. 16 October 1977. J. N. Layne. Verified by J. N. Layne. Archbold Biological Station, Florida (ABS 44). New county record. Hillsborough Co: Brandon, jct. SR 60 and Parsons Ave. 26 March 1978. JSG 7023. Hillsborough Co: Lutz, US 41. 10 September 1978. No voucher specimens taken. Hillsborough Co: Plant City, jct. I-4 and McIntosh Road, Stuckey's. 31 October 1977. JSG 6900. Hillsborough Co: Thonotosassa, Lake Thonotosassa Fish Camp on SR 580. 21 July 1977. No voucher specimens collected. Species taken in every Hillsborough County city that has been searched; only known from urban areas. Lee Co: Boca Grande, Gasparilla Island, jct. East Ave. and 11th St. 17 August 1977. H. Curtis. Verified by J. S. Godley. Lee Co: Fort Myers, 1548 Barcelona St. 17 August 1977. H. Curtis. Verified by J. S. Godley. H. Curtis reports species common in Fort Myers, Boca Grande and Sanibel Island. Manatee Co: Bradenton, jct. US 41 and 57th Ave. W. 10 September 1977. JSG 6761. New county record. Common throughout city. Marion Co: Ocala, jct. I-75 and US 27 at Howard Johnson's Motel. 20 September 1979. D. R. Jackson. Verified by J. S. Godley. New county record. D. R. Jackson reports thriving colony at Howard Johnson's but could not find species at several other locations in Ocala; may be recently established. Orange Co: Orlando, Belle Isle, 2123 Nela Ave. 19 June 1978. JSG 7036. New county record. Species established, but patchily distributed in the Orlando area. Osceola Co: jct. I-4 and SR 192, Hyatt House Motel World. 12 October 1977. JSG 8155-56. New county record. Pasco Co: New Port Richey, 58 Blue Heron Drive. 16 April 1977. JSG 6686. New county record. Pinellas Co: Clearwater, St. Petersburg Junior College campus. 21 August 1977. JSG 6748-49. Pinellas Co: Oldsmar, *ca* 1 km E SR 584 on SR 580, McDonald's restaurant. 21 August 1977. JSG 6751. Pinellas Co: Safety Harbor, Safety Harbor City Hall. 21 August 1977. JSG 6750. Polk Co: Bartow, Polk County courthouse. 9 June 1979. JSG 8151. New county record. Moderately common in suburbs. Polk Co: Lakeland, jct. SR 92 and Wabash Ave. 31 November 1977. JSG 6901. Species also seen by F. E. Lohrer in south Lakeland on 14 January 1976. Polk Co: jct. I-4 and US 27, Howard Johnson's Motel. 7 October 1979. JSG 8152-53. Sarasota Co: Lido Key, Limetree Motel. 11 September 1977. JSG 6765. New county record. Common in urban areas of Lido Key and Longboat Key. Sarasota Co: Sarasota, jct. US 41 and SR 780. 11 September 1977. JSG 6764. Species also collected in Sarasota at Ringling Museum on 20 April 1978 by F. E. Lohrer (ABS 82) and at 37 South McIntosh Rd. on 25 November 1978 by D. T. Gross; observed on 23 December 1979 by F. E. Lohrer at Turtle Bay Park, Siesta Key, Sarasota.

The above records document that *Anolis sagrei* now inhabits much of peninsular Florida as disjunct colonies generally confined to urban settings. The new localities from Look Road (SR 94) in Monroe County, and east of Goulds, Homestead and Florida City in Dade County suggest that *A. sagrei* is invading some semi-natural habitats in southern Florida. However, all of these sites represent either road-side localities or habitats dominated by populations of introduced Brazilian peppertree or Australian pine.

We are most familiar with the distribution of *A. sagrei* in the Tampa Bay area, where it has been established since about 1942 (Oliver, 1950). In this region the lizard is now common in every urban area that has been searched, but no specimens have been collected from native habitats. Considering only the region within a 75 km radius of Tampa, and assuming that the species occurs only in cities where it has been collected (N=13), we estimate conservatively that this population of *A. sagrei* has invaded *ca* 1200 sq km of urban habitat in about forty years. As many more distant localities probably represent introductions from the Tampa parental stock (see below), the present range of this population easily could be twice the above estimate.

Earlier reports (Oliver, 1950; King, 1960) suggested that *A. sagrei* was restricted to major Florida seaports (i.e., Key West, Miami, Tampa), where ships bound with cargo from Cuba accidentally introduced the species. Although within-state coastal shipping and pleasure boating may have been responsible for some additional coastal introductions, this mode of transport cannot explain the occurrence of *A. sagrei* at the numerous inland localities (N=17), and probably does not explain most coastal locations.

We suggest that the subsequent dispersal of *A. sagrei* from the known mainland ports of entry (i.e., Miami and Tampa) has been accomplished by two major modes of "rafting:" (1) the transport of propagules on vehicles (cars, trucks, etc.) operating between these source areas and other urban centers within the state, and (2) the transport of adults and/or eggs in ornamental plants, especially via the commercial plant nursery trade. The species commonly perches and sleeps on vehicles or ornamental plants, and is readily transported in this manner. In addition, most of the isolated localities for *A. sagrei* are cities or gas stations, motels and restaurants located along major highways (e.g., I-4, I-75, US 19, US 27, US 41), all of which have high volumes of traffic and are planted with shrubbery. In this respect, the high incidence of *A. sagrei* colonies among coastal cities probably reflects the distribution and movements of human populations in Florida, not habitat preferences of the lizard or multiple invasions from the West Indies.

The apparent affinity of this lizard for urban "islands" suggests that the present pattern of colonization of *A. sagrei* in Florida can be interpreted best in terms of island biogeographic theory (Mac Arthur and Wilson, 1967). The probability of successful *A. sagrei* colonization at a site appears to be determined primarily by (1) distance from source areas and (2) island (=city) size. Rates of rafting are, in turn, dependent upon human and plant traffic patterns within the state, and lizard population size. Of course, the establishment and subsequent population expansion at one location would increase the probability of successful introductions onto neighboring urban islands, creating an archipelago effect.

Acknowledgments

We thank H. W. Campbell, H. Curtis, K. B. Godley, D. T. Gross and D. R. Jackson for providing locality records and/or specimens. We also thank G. E. Woolfenden and A. Schwartz for commenting on the manuscript.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

NOTES ON CAPTIVE REPRODUCTION AND BEHAVIOR IN THE MEXICAN CANTIL *(Agkistrodon bilineatus)*

There is little published information regarding reproduction and feeding behavior of the Mexican cantil, *Agkistrodon bilineatus*. Most publications have dealt with field records that contain taxonomic and/or geographical data (Bogert and Oliver, 1945; Burger and Robertson, 1951; and Henderson, 1978). The following account includes information regarding the reproduction and diet of captive *A. bilineatus*.

On 18 April, 1966, the Oklahoma City Zoo received a subadult male from an unknown source and on 1 June, 1973, received two adult females from an unknown locality. Upon arrival, each animal was quarantined in separate holding cages for approximately 30 days. In early fall 1973, the two females and male were placed in a glass-fronted wooden enclosure measuring 79 x 61 x 46 cm that was sparsely decorated with polyethylene vegetation, rocks, and gravel substrate. Measurements recorded in July, 1979, were as follows: female A total length 854 mm, weight 519 g; female B tl 879 mm, weight 445 g. Measurements were not recorded for the male although he was judged to be of similar size (Mike Blakely, pers. comm.).

On 24 June, 1973, 12 young were found with female B and 15 days later, on 9 July, 1973, six young were found with female A. Six of 18 died shortly after birth. Measurements were not recorded. The only published estimate of mean litter size is 12 (Fitch, 1970).

On 28 April, 1976, at approximately 0730 hrs., a routine check of the cage disclosed that the male and female B were engaged in copulation. They were connected for about nine hours (Rusty Grimpe, pers. comm.). No further courtship or copulation was observed and on 26 December, 1976, the male died of post-operative trauma after removal of a tumor from the mid-dorsal area.

Both females were kept in the same display cage and on 28 May, 1977, at 0900 hrs., nine young were discovered beneath an artificial plant in the rear portion of the exhibit. All appeared in good condition and were actively shedding skin. No fluids or membraneous tissue were detected. Although female A was involved in the last observed copulation, I could not definitely determine which female was the mother.

The time lapse between the observed mating on 28 April, 1976, until parturition on 28 May, 1977, gives a possible gestation period of 395 days. Such a long range might suggest sperm retention or delayed fertilization although additional matings could have occurred.

The juveniles were basically reddish brown with broad light-edged crossbands against a light brown background. As in some other juvenile pit vipers (Neill, 1960), a large portion of the posterior tail region of each animal had a characteristic yellowish-green color. No measurements were recorded for these juveniles.

From the beginning, the young were quite reluctant to feed, though they were offered small lizards *(Anolis carolinensis)*, frogs *(Acris crepitans blanchardi* and *Hyla versicolor)*, newborn mice and various insects. The first feeding occurred during the night of 17 June, 1977, when four of the nine juveniles ate one newborn mouse each. Unexplainably, food was refused for the next eight weeks and by 21 August, only two snakes remained alive.

On 27 August, 1977, both surviving young were offered one juvenile *Nerodia r. rhombifera* each. The water snakes were born at the Herpetarium in June, 1977, and were only slightly smaller than the cantils. On the following morning, a check of each cage revealed that both *Nerodia* had disappeared while each *A. bilineatus* was noticeably larger. As of January, 1979, one juvenile remained alive, was feeding on brown snakes (*Storeria* spp.) and ringneck snakes (*Disdophis* spp.), and had only recently accepted small, furred mice (Frank Bryce, pers. comm.).

Bogert and Oliver (1945) reported that the stomach contents of one *A. bilineatus* from Sonora contained an adult *Imantodes gracilimus*. Henderson (1978) found a mass of mammal hair in the lower intestine of a Belize specimen. It is possible that the cantil is an opportunistic feeder, as Conant (1975) suggests for *A. piscivorus*. Unfortunately, there are no extensive records concerning food habits in the wild.

Allen (1949) and Neill (1960) confirmed the use of caudal lures as a response to prey for juvenile *A. bilineatus*. Although most of the captive juveniles often held the tail vertically, tail undulation was observed rarely. Slight tail twitching was sometimes observed when various frogs were introduced, but these potential prey were not bitten. Tail twitching was not observed when other prey items (lizards, mice, snakes, insects, *etc.*) were introduced. However, as previously mentioned, food was consumed at night and active caudal luring could have taken place at twilight or even nighttime, although one would not expect a primarily visual lure to be used in total darkness. Allen (1949) believed that the tail is kept down at night.

Acknowledgments

I would like to thank Rusty Grimpe, Mike Blakely, and Darell Pickering for help with the data collection. Also, I would like to give special thanks to Dr. Douglas Mock and Mr. Bern Tryon for commenting on the manuscript.

LONGEVITY RECORDS AT THE OKLAHOMA CITY ZOO

How long reptiles and amphibians live has long been an interest of herpetologists, particularly to those involved with public institutions such as zoos. Bowler (1977) was the first to attempt a comprehensive listing of longevity records of reptiles and amphibians maintained in living collections within the United States. The following is a listing of what we feel are significant records of specimens in the herpetological collection at the Oklahoma City Zoo (OCZ). All specimens listed were alive at the time this report was prepared and were received as wild-caught adults when they entered the collection at OCZ.

OCZ Number	Species	Years	Months	Days (as of 11/18/79)
809-01	*Litoria caerulea*	10	2	23
823-02	*Ceratophrys calcarata*	12	2	18
4722-01	*Phelsuma madagascariensis kochi*	4	4	3
4741-02	*Varanus prasinus*	4	4	18
999-02	*Cordylus giganteus*	10	2	18
975-01	*Anolis equestris*	12	10	16
3185-02	*Python boeleni*	6	4	18
1045-01	*Python curtus brongersmai*	14	3	18
1061-01	*Lampropeltis c. calligaster*	12	5	18
4719-03	*Lampropeltis triangulum gaigeae*	4	4	18
1798-02	*Oxybelis aeneus*	8	3	18
1120-02	*Sistrurus catenatus tergeminus*	13	5	18

SECOND EUROPEAN CHELONIAN SYMPOSIUM, 1981
to be held in
THE DEPARTMENT OF ZOOLOGY, UNIVERSITY OF OXFORD
Saturday/Sunday, 3rd and 4th October 1981

The Symposium will be held in conjunction with the International Herpetological Congress, 3rd-9th October 1981, and will follow-on from the Inaugural Meeting of members of the IUCN/SSC Tortoise Specialist Group on 1st and 2nd October 1981. Investigations on terrestrial forms will primarily be considered at the Symposium, but papers on fresh-water species may also be submitted, either as part of the Symposium or as part of the International Congress. There will be Proceedings.

The language of the International Congress is English, and also of the Symposium. In exceptional cases and in deference to the First Symposium, papers in French and, possibly, German will be considered, provided a written Summary in English is available for circulation.

Titles of papers to be offered, with a written summary, should be sent to the Symposium organiser: Dr. M.R.K. Lambert, Secretary, British Herpetological Society, c/o Zoological Society of London, Regent's Park, London NW1 4RY, England, no later than 10th September 1981. Papers will not be considered unless a written summary is submitted, and should not be more than 30 minutes. Requests for further details should be sent to the Congress organiser: Mr. J. Coborn, Zoo Director, Dudley and West Midlands Zoological Society, 2 The Broadway, Dudley, West Midlands DY1 4QB, England. Oxford accommodation advice is available.

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted. Citations should be sent to

No material was received for this issue. The section is being revised by coordinator Dinardo, and readers are referred to notes on page 74 of this issue.

SSAR PUBLICATIONS

FACSIMILE REPRINTS IN HERPETOLOGY

Initiated in 1961, this series serves to make rare and important books and papers on amphibians and reptiles available once again to persons working in the field. All reprints are exact photolithographic facsimilies; all are paperbound unless otherwise indicated.

•BELL, T. 1843. Herpetology of the "Beagle". Part V of Darwin's classic **The Zoology of the Voyage of the H.M.S. Beagle** contains descriptions of 46 species (25 being new) of amphibians and reptiles collected on that renown expedition. 100 pages, 20 plates, 8½ x 11 in.
Introduction by Roberto Donoso-Barros — paperbound $10.00 ☐ clothbound 15.00 ☐

•BOJANUS, L. H. 1819-1821. Anatome Testudinis Europaeae. The classic atlas of turtle anatomy, with an introduction by A. S. Romer. 200 pages (7 x 10 in.) plus 40 plates (10 x 14 in.)
paperbound $25.00 ☐

•BOULENGER, G. A. 1877-1920. Contributions to American Herpetology. A series of collected papers from various journals; complete in 18 parts totaling about 900 pages. Illustrated; 6 x 9 in.

Introduction and Table of Contents: Parts 1-10, 1877-1897, plus personal comments on Boulenger by J. C. Battersby.	$ 2.00 ☐
Part 1: 1877-1881, 6 papers, 32 p.	2.00 ☐
2: 1882-1883, 12 papers, 48 p.	2.00 ☐
3: 1884-1885, 10 papers, 44 p.	2.00 ☐
4: 1886-1887, 10 papers, 56 p.	2.00 ☐
5: 1888, 13 papers, 32 p.	2.00 ☐
6: 1889-1890, 10 papers, 48 p.	2.00 ☐
7: 1891-1893, 11 papers, 44 p.	2.00 ☐
8: 1894, 5 papers, 40 p.	2.00 ☐
9: 1895-1896, 11 papers, 52 p.	2.00 ☐
10: 1897, 2 papers, 56 p.	2.00 ☐
Table of Contents: Parts 11-18, 1898-1920	2.00 ☐
11: 1898, 4 papers, 52 p.	2.00 ☐
12: 1899-1900, 9 papers, 48 p.	2.00 ☐
13: 1901-1902, 7 papers, 34 p.	2.00 ☐
14: 1903-1904, 8 papers, 28 p.	2.00 ☐
15: 1905-1911, 12 papers, 42 p.	2.00 ☐
16: 1912-1913, 6 papers, 46 p.	2.00 ☐
17: 1914-1919, 8 papers, 38 p.	2.00 ☐
18: 1920, 3 papers, 64 p.	2.00 ☐
Index, 44 p.	2.00 ☐
Complete set, 18 pts. plus index	$35.00 ☐

•BULLETIN OF THE ANTIVENIN INSTITUTE OF AMERICA. Volumes 1-5, 1927-1932. Complete set of an important journal devoted to the taxonomy, biology and distribution of snakes, lizards, salamanders and crocodilians. 575 pages, 163 photographs, maps, index.
paperbound $25.00 ☐ clothbound 28.00 ☐

•CAMP, C. L. 1923. Classification of the Lizards. The foundation of modern lizard systematics; with a new preface by the author and an extensive review of current literature by Garth Underwood, plus index. Illustrated; 5½ x 8½ in.; 220 pages.
paperbound $20.00 ☐

•CHANG, M. L. Y. 1936. Amphibiens urodeles de la Chine. The standard work on Chinese salamanders with a new checklist by Arden Brame. Illus.; 5½ x 8½ in.; 168 pages, 5 plates.
paperbound $ 8.00 ☐

•COPE, E. D. 1864. Papers dealing with Anuran Taxonomy. Reprinted from The Proceedings of the Academy of Natural Sciences of Philadelphia and The Natural History Review. 20 pages.
paperbound $2.00 ☐

•COPE, E. D. 1871. Catalogue of Batrachia and Reptilia obtained by McNiel in Nicaragua; Catalogue of Reptilia and Batrachia obtained by Maynard in Florida. 8 pages.
$1.00 ☐

•COPE, E. D. 1892. The osteology of the Lacertilia. An important contribution to lizard anatomy, reprinted from the Proceedings of the American Philosophical Society. 42 pages, 6 plates.
$2.00 ☐

•COWLES, R. B. and C. M. BOGERT. 1944. A preliminary study of the thermal requirements of desert reptiles. This influential paper is reprinted from AMNH Bulletin 83, article 5 plus an introductory essay by F. Harvey Pough. 34 pages, illustrated.
$3.00 ☐

•D'ORBIGNY, A. 1847. Voyage dans l'Amerique meridionale. This extract comprises the complete section on reptiles and amphibians. All text and plates have been reproduced in their original size. 10 pages, 8½ x 11 in., 9 plates.
$3.00 ☐

•DUNN, E. R. 1926. Salamanders of the Family Plethodontidae. A recognized classic treatment of the plethodontid salamanders, including tropical and European species. A new introduction by David Wake and Arden Brame provides a modern appraisal of this work. Illus., 6 x 9 in.; 472 pages, 3 plates, 86 maps, index.
paperbound $15.00 ☐ clothbound 20.00 ☐

•ESCHSCHOLTZ, F. 1829-1833. Zoologischer Atlas (herpetological sections). Descriptions of new reptiles and amphibians from California and the Pacific. 8½ x 11 in.; 32 pages
$2.00 ☐

•De La ESPADA, D.M.J. 1875. Vertebrados del Viaje al Pacifico. A reprint of the most famous of Espada's works in herpetology. An essential reference for anyone interested in the amphibians of South America. With an introduction and biography by J. M. Savage. 208 pages, 6 plates.
clothbound $15.00 ☐

•FITZINGER, L. J. 1843. Systema Reptilium. An important nomenclatural landmark for herpetology, including amphibia as well as reptiles; world-wide in scope. 6 x 9 in.; 128 pages, portrait.
Introduction by Robert Mertens — paperbound $11.00 ☐ clothbound 15.00 ☐

•GLOYD, H. K. 1940. The Rattlesnakes Genera Sistrurus and Crotalus. A study in zoogeography and evolution. Introduction by H. M. Smith and H. S. Harris. Jr. 300 pages plus 31 plates of photographs; Index. 7 x 10 inches.
clothbound $20.00 ☐

•GRAY, J. E. 1825. A synopsis of the genera of reptiles and Amphibia. 32 pages
paperbound $2.00 ☐

•GRAY, J. E. 1831-1844. Zoological Miscellany. A privately printed journal, devoted mostly to descriptions of amphibians, reptiles and birds from all over the world. This reprint comprises the entire series and includes a new introduction and biography of Gray by Arnold Kluge. Illus., 5½ x 8½ in.; 86 pages, 4 plates.
paperbound $ 6.00 ☐ clothbound 10.00 ☐

•HOLBROOK, J. E. 1842. North American Herpetology. Five volumes bound in one. This is an exact facsimile of the second edition, including all 147 plates, 19 reproduced in full color. An introduction, a biography by Dr. and Mrs. Worthington and a new portrait of Holbrook by David Dennis are added. 1000 pages. 8½ x 11 inches.
clothbound $60.00 ☐

•JUNIOR SOCIETY OF NATURAL SCIENCES (CINCINNATI, OHIO). 1930-1932. Herpetological papers from the Society's Proceedings, with articles by Weller, Walker, Dury and others. 56 p.
paperbound $2.00 ☐

•KIRTLAND, J. P. 1838. Zoology of Ohio (herpetological portion). 8 pages.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

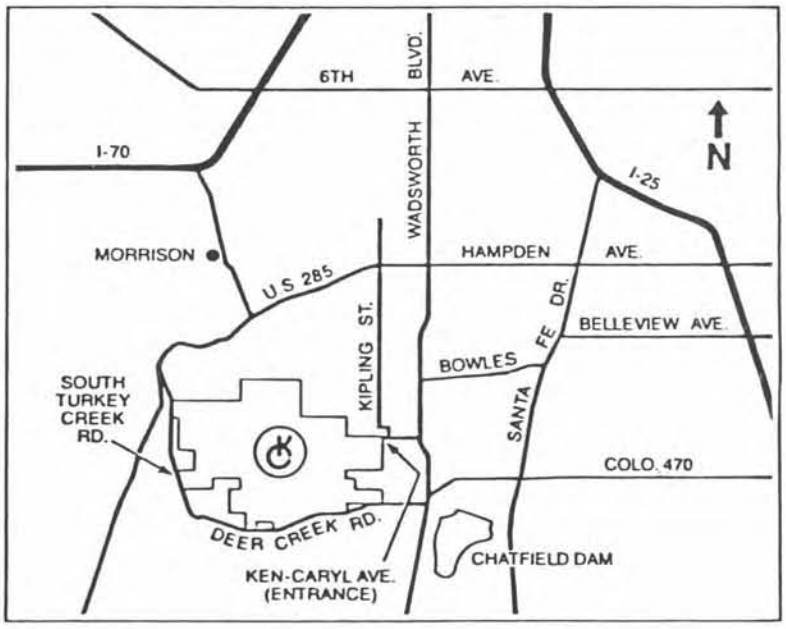
OBSERVATIONS ON *CROTALUS V. VIRIDIS* (RAFINESQUE) AND THE HERPETOFAUNA OF THE KEN-CARYL RANCH, JEFFERSON COUNTY, COLORADO



The Ken-Caryl Ranch is a ten thousand acre property located in central Jefferson County, about ten miles southwest of Littleton, Colorado (Map 1). Until the early 1970's, it was essentially an undisturbed wilderness. Residential development was begun on the ranch in the mid-1970's. At that time, the presence of large numbers of rattlesnakes on the property became highly undesirable. Therefore, a rattlesnake control program was initiated in 1976. Information was collected on the prairie rattlesnake *(Crotalus viridis viridis)* as well as other reptiles and amphibians during the course of the work, which is ongoing. The project consists basically of summertime collecting when possible, plus den location and subsequent capture of rattlesnakes present in spring and fall. Rattlesnakes collected are either donated to local universities for research purposes or relocated.

Ken-Caryl Ranch is an exceptionally large and diverse property. It is situated on Colorado's Front Range. The ranch extends one and one-half miles east of the Dakota Hogback (the first uplift) and west into the foothills some two and one-half miles. It contains elements of mixed prairie, mountain shrubland and coniferous forest habitat types, as well as some riparian situations. Elevations range from 5,800 to nearly 8,000 feet.

Ken-Caryl Ranch provides excellent habitat for the prairie rattlesnake. Consequently, a large population has developed. It is known from virtually throughout the property. Rattlesnakes are most abundant in the prairie dog towns, and on the hogbacks to the west. However, a few individuals have been collected on forested northern slopes at 7,500 foot elevations. Field observations indicate that much of the eastern population of *viridis* spends the summer in the prairie dog towns. In the fall, these snakes migrate to den sites on the west side of the Dakota Hogback. Unlike snakes in some areas, Ken-Caryl's rattlers do not hibernate in prairie dog burrows to any major extent.

In the late spring and summer, the snakes again disperse outward from the dens. Prairie dog towns provide many of them with excellent summer habitat. They utilize the burrows for shelter and prey upon mice *(Peromyscus)*, ground squirrels *(Citellus)*, voles *(Microtus)*, rabbits *(Sylvilagus)*, and nestling passerines of several species. Rattlesnakes will often rest in the mouth of a prairie dog burrow, retreating into it when threatened.

Adult *viridis* from Ken-Caryl Ranch range from 28 to 34 inches in total length. The largest example collected to date was 45 inches long. Adults are highly variable both in temperament and coloration. They range from light tan to greenish to dark brown. Their aggressiveness is also highly variable. Some individuals are quite docile — declining to rattle or strike, even when captured. Others will lash out at intruders when approached. Most specimens exhibit behavior between the two extremes.

Map 1. Vicinity map of the Ken-Caryl Ranch showing relationship of major highways. Approximate scale: 1 inch = 5.5 miles.

One would expect *viridis* to be on a biennial reproductive cycle at this latitude (Fitch, 1970). Alternate-year breeding (in a given female) has been observed in South Dakota, Wyoming, Utah, and California (see Klauber, 1972). However, the period of activity for *viridis* is considerably longer here than in, say, South Dakota. Thus, annual breeding, which does occur farther south, is at least a possibility. I have observed neither copulation nor parturition on Ken-Caryl Ranch. Young of the year are occasionally seen in the fall. They may or may not be near major denning areas. When observed at a denning ground, they are usually near small crevices, rather than at the holes used by the adults. A. M. Jackley (in Klauber, 1972), observed that young born near the den would not follow the adults to it in the first year. Klauber (1972) suggested that they would not hibernate in a fissure-type den with the adults due to the risk of being crushed. A large number of juveniles are undoubtedly overlooked in collecting activities. Bullsnakes *(Pituophis melanoleucus sayi)* and racers *(Coluber constrictor flaviventris)* often den in the same crevices as *viridis*.

To date, four major denning areas have been located on Ken-Caryl Ranch. All are situated in holes or crevices of sedimentary rock outcroppings. The Massey Draw and Dutch Creek dens are on the southern exposures of water gaps (canyons) in the Dakota Hogback. Denning crevices are situated at the base of the wall formed by the caprock. A talus slide in the Ft. Hays member of the Niobrara limestone formation forms a third den (the Niobrara formation lies immediately east of the Dakota Hogback). The fourth den is located in the Lytle sandstone formation on the western aspect of the Dakota Hogback. This den is situated about midway between the base of the ridge and the top rather than being associated with the caprock. Because of its remote location, it is not being disturbed at this time. Also, it is under periodic investigation by myself and students from the University of Colorado.

The Massey Draw, Dutch Creek and Niobrara dens have produced a total of 162 rattlesnakes to date. The snakes were collected by hand or trapped. Trapping is accomplished by using a box with a one-way gate placed in the den entrance. These traps can be highly effective if the den entrance is suitable.

Rattlesnake traps are most useful in the spring. They are placed in the den entrances throughout the emergence period. Traps are checked and emptied regularly. Fall trapping is possible, but best employed after the snakes have arrived at the dens. It is usually difficult to provide a way for the snakes to enter the

traps from outside the dens. If the traps are in place too early, new arrivals will be unable to enter the dens and may move to other areas. Thus, traps are placed in den entrances during late October to capture snakes emerging to bask. Hand collection is used to supplement trapping.

Collecting and trapping has virtually eradicated *viridis* from the Massey Draw and Niobrara dens. This is evident from the declining numbers of snakes captured each season (see Table 1).

Rattlesnakes have also been collected in non-denning situations throughout the ranch. These summer collections have produced 135 snakes to date. Summer collections are less effective in population control, but may suggest the location of dens. The vast majority of these captures have been on the eastern half of the ranch. Relatively few snakes have been collected in the foothills. Apparently, population densities decrease as elevation increases.

Locating rattlesnake dens is surprisingly difficult. The broken topography of the Front Range provides such an apparent abundance of denning habitat that locating them by the appearance of the strata is not possible. This means that all likely areas must be searched in the spring and fall.

Dens are usually identifiable only by the presence of snakes. Thus, the would-be collector must be fortunate enough to walk within a few yards of the den when the snakes are basking. Basking en masse seems to be rare on the ranch. Also, the snakes often bask in surface crevices, beneath shrubs, and under rocks near the den entrance. Though the Massey Draw dens produced 54 *viridis* in the fall of 1977, no more than 3 snakes were ever observed at any one instant. Large aggregations of basking snakes, which do occur in the plains states, are apparently rare in this area.

The Massey Draw and Dutch Creek dens have certain similarities. As previously stated, both are associated with water gaps in the Dakota Hogback. These gaps occur at fairly regular intervals along this north-south ridge. They are typically spaced less than 2 miles from one another. Where adjacent to suitable habitat, these gaps probably provide among the best denning sites. The advantages they exhibit are abundance of crevices, shelter from north winds, dryness, and warm, sunny, southern slopes. Thus, it would be easy to assume that water gaps are simply *the* denning areas. However, this is not entirely true. The other two dens known on the property are not associated with water gaps. They are simply rock outcroppings with suitable crevices. Their geologic origin, type of fractures, vegetation, elevation and slope are fairly dissimilar. It is the presence of suitable crevices that is the snakes' number one priority in choosing a den. Proximity to summer feeding grounds is undoubtedly also important.

On Ken-Caryl Ranch, rattlesnakes have been seen at dens as early as 28 March and as late as 16 November. In the fall, snakes begin to arrive at the dens in late September. Their migration continues through most of October. In the spring, the most productive period to hunt is from early April through mid-May.

Table 1. Summary of rattlesnakes collected over a three-year period at Ken-Caryl Ranch.

† Dens are not hunted in the summer
§ Den location unknown at the time

Obviously, emergence of the snakes will be affected by weather conditions. Temperatures must be at least in the mid-60's for the snakes to bask. Dens with west or southwest exposures are best visited between noon and 6 p.m. A summary of the phenology of rattlesnakes, as observed on the Ken-Caryl Ranch, is shown in Table 2. A complete list of reptiles and amphibians identified to date is shown in Table 3.

Discussion

It is now apparent that there are some significant differences between dens on Ken-Caryl and the more classical *viridis* dens of plains country. In South Dakota, for example, several hundred snakes have been taken at a single denning ground. Dens are often widely scattered and snakes must sometimes travel a mile or more to return to them (Jackley, 1947). One might term such a situation "regional" denning. That is, a large population hibernates together and disperses over a wide area during the summer. The Massey Draw den, actually six crevices along 600 feet of wall, could be considered a regional den. It was used by about 150 *viridis* in recent times. My observations indicate many, if not most, of its residents dispersed eastward for a mile or more into the prairie dog towns.

The other three dens on the ranch might be termed "local" dens. Here populations of say, 35 or fewer snakes hibernate together and disperse shorter distances into the shrublands of the hogback. The Dutch Creek and Talus Slide dens are situated only 0.57 miles from one another.

The paucity of snakes at these smaller dens can't be attributed to a low overall population. Prairie rattlesnakes are as abundant on the ranch as anywhere I have hunted them. Obviously, numbers of snakes at a particular hibernaculum could be restricted by the size of the cavity itself. The den populations documented to date cannot possibly account for all the snakes present during the summer. Thus, there must be several more of these local dens, each used by a sub-population with a fairly short dispersal radius. It seems that, along the hogbacks, denning crevices are readily available and the snakes need not travel far or concentrate greatly. Of course, these observations are somewhat speculative. Confirmation would require capturing, marking, releasing, and recapturing a considerable number of snakes. Unfortunately, releasing rattlesnakes would not be very popular on the ranch.

If it is correct that a small percentage of the total population uses each denning area, then effecting control will be difficult. A population is most vulnerable to control when it is greatly concentrated at a few dens. If a given population is denning in a number of scattered locations, in relatively small concentrations, removing a high percentage of the snakes will be difficult and time consuming. The selective and reproductive implications of this scattered-denning behavior are also interesting to consider.

Conclusion

There are certainly rattlesnake dens as yet undiscovered on Ken-Caryl Ranch. Continuing abundance and summer distribution of *viridis* on the ranch strongly support this conclusion. There is good evidence that there are a greater number of dens, with smaller concentrations of snakes in this area than might be expected. Rattlesnakes are also occasionally seen in the foothills over three miles from the hogback dens. Thus, there must be dens in these foothill areas. Yet, no dens have been located in any Precambrian (granitic) formations on the ranch.

Undoubtedly, rattlesnake captures made to date have reduced the total population. Perhaps more important, location and eradication of dens proximal to human habitations has resulted in localized population reduction. If this results in a diminished snakebite

Table 2. Phenology of rattlesnake activities over a one-year period at Ken-Caryl Ranch.

January 1 to Late March
Snakes in hibernation. Encounters very rare.

Late March to Late April
Basking at the dens occurs when weather conditions are favorable. Most snakes re-enter the den each evening.

Late April to Late May
Snakes gradually begin to disperse from the denning areas onto summer ranges.

Late May to Mid-September
Snakes are feeding, shedding, breeding, and giving birth on the summer ranges.

Mid-September to Early October
Snakes gradually begin to migrate back to dens.

Early October to Early November
Snakes are arriving at the dens, basking occurs when weather conditions are favorable.

Early November to December 31
Snakes in hibernation, encounters very rare.

Table 3. Reptiles and amphibians recorded from the Ken-Caryl Ranch, Jefferson County, Colorado. Nomenclature follows Smith, *et al.*, 1965.

REPTILES

SNAKES

Prairie rattlesnake (*Crotalus viridis viridis* Rafinesque).
Ubiquitous; most common below 7,000 feet in rocky areas and prairie dog towns.

Bull snake (*Pituophis melanoleucus sayi* Schlegel).
Most common in prairie dog towns and on the hogbacks; rarely in the foothills to 7,000 feet.

Eastern yellow-bellied racer (*Coluber constrictor flaviventris* Say).
Rocky areas of the hogbacks; common.

Western garter snake (*Thamnophis elegans vagrans* Baird and Girard).
Moist environs of the western foothills.

Red-sided garter snake (*Thamnophis sirtalis parietalis* Say).
Occasional in eastern riparian areas.

Western plains garter snake (*Thamnophis radix haydeni* Kennicott).
Moist areas east of the foothills.

Smooth green snake (*Opheodrys vernalis blanchardi* Grobman).
Rare; known from one hillside, southern exposure, elevation 7,200 to 8,000 feet.

Western hognose snake (*Heterodon nasicus nasicus* Baird and Girard).
Uncommon; known from 2 specimens in Deer Creek drainage between hogbacks and foothills.

Central plains milk snake (*Lampropeltis triangulum gentilis* Baird and Girard).
Secretive and uncommon; known from 4 specimens from 2 rocky canyons.

LIZARDS

Northern prairie lizard (*Sceloporus undulatus erythrocheilus* Maslin).
Common in rocky areas of the hogbacks and foothills.

Prairie racerunner (*Cnemidophorus sexlineatus viridis* Lowe).
Locally common in dry, sandy areas below 7,000 feet.

Northern short-horned lizard (*Phrynosoma douglassi brevirostre* Girard).
Rare; known only from plains prairie dog towns.

TURTLES

Painted turtle (*Chrysemys picta belli* Gray).
Introduced? Known from one specimen in pond, western foothills meadow.

AMPHIBIANS

Tiger salamander (*Ambystoma tigrinum mavortium* Baird).
Locally common, but secretive in plains and western foothills; subterranean or aquatic most of the year.

Northern leopard frog (*Rana pipiens brachycephala* Cope).
Common in drainages east of the foothills.

Boreal chorus frog (*Pseudacris triseriata maculata* Agassiz).
Common; vocal resident of western foothills ponds.

danger, then the objective of the program is being met.

In my opinion, complete eradication of *viridis* from the ranch is neither feasible nor desirable. Rattlesnakes, like all wildlife species, serve a useful purpose in the ecosystem. In remote, undisturbed areas, their presence is an asset, not a liability.

AN ALBINO EASTERN GARTER SNAKE, *THAMNOPHIS SIRTALIS SIRTALIS*, FROM WESTERN MASSACHUSETTS

Wright and Wright (1957) stated in their section on abnormal coloration of *Thamnophis s. sirtalis* that "several albinos have been recorded," but report only the one case of a partial albino attributed to Eaton (N.Y., 1945).

On 22 August 1979, a newborn albino specimen of *T. s. sirtalis* was collected by a local youngster in or about the environs of a woodpile in a semi-urban area of Pittsfield, Berkshire County, Massachusetts. The specimen was brought to the Berkshire Museum in Pittsfield where it underwent its post-natal shed, but steadfastly refused food. On 5 September 1979, the snake was given to R. D. Bartlett, and was immediately housed in a 10 gallon aquarium with adequate areas of seclusion. Although no interest was displayed in food introduced to the cage, the animal did feed that night upon an earthworm while both the specimen and the worm were being handheld. Additional food was accepted daily for the next week when offered in like manner.

On 13 September 1979, the specimen began tracking and consuming earthworms introduced to its cage, and on 16 September 1979 it accepted two small fish. Subsequently, the specimen has eagerly tracked and consumed earthworms, small fish, *Plethodon c. cinereus, Eurycea b. bislineata,* and *Hyla c. crucifer.* Although newborn mice have been offered, they have, to date, been refused after a cursory investigation by the snake.

Size on the date of collection was 190 mm (est.), which compared favorably with normally colored newborns from other areas. On 26 October 1979, after a second ecdysis, the specimen measured 240 mm in overall length.

Pattern is strongly evident, the background coloration and stripes being chalk-white. Between the mid-dorsal and lateral stripes are two rows of alternating light pink spots. Temporal blotches are light pink, this becoming darker towards the posterior terminus of each blotch. Eyes are completely pink.

FIRST RECORD FOR THE STRIPED COLOR MORPH OF *Plethodon cinereus* FROM A LAKE ERIE ISLAND

High percentages of the unstriped morph of the red-backed salamander, *Plethodon cinereus,* have been reported from northern Ohio and include a monomorphic unstriped population from South Bass Island (located in the western basin of Lake Erie), Ottawa County, Ohio (Pfingsten and Walker, 1978).

During investigations on the ecology of *P. cinereus* at Victory Woods (1.7 km W Put-In-Bay), South Bass Island, 131 unstriped and 1 striped *P. cinereus* were collected. The striped morph (SV 25mm) was found with several unstriped morphs under a decaying log in typical woodland habitat for *P. cinereus* (Heatwole, 1962). This specimen, being the first record for the striped morph from South Bass Island, was released at the capture site after being photographed.

The nearest *P. cinereus* populations in northern Ohio have greater percentages of striped morphs (7-80% striped; Pfingsten and Walker, 1978) and are now separated from South Bass Island by at least 4 km of water. Twelve thousand five hundred years ago though (after the last glaciation), the bottom of Lake Erie was virtually dry and was covered with forests (Forsyth, 1973). During this period, South Bass Island could have been populated by salamanders following the retreating glacier. The subsequent reflooding of the western basin (3,500 to 4,000 years ago) would have isolated South Bass Island with its *P. cinereus* population (Forsyth, 1973). The progression toward a monomorphic unstriped condition in this isolated population could then have occurred simply by genetic drift. Hence this lone striped *P. cinereus* may represent a relict gene in the population.

Acknowledgments

The field work would not have been possible without the help of T. Bonace, R. Carter, M. Duffy, D. Michael, and P. Zock. Dr. G. Dalrymple constructively criticized the manuscript.

AN INTERGRADE *Lampropeltis triangulum* FROM WEST TEXAS

On 8 August, 1978, the authors secured a DOR specimen of *Lampropeltis triangulum* during the late morning on Highway 90, 0.8km west of Sanderson, Terrell Co., Texas. Upon examination the specimen appeared to be an intergrade between *L. t. celaenops* and *L. t. annulata.* Personal communication with Dr. Kenneth L. Williams further indicates that this is the first specimen of *L. triangulum* recorded from this area. It is deposited in the University of Michigan Museum of Zoology under the number UMMZ 156483.

The data on lepidosis and coloration of the specimen are given below:

Supralabials 7-7; infralabials 7-8; preoculars 2-?; postoculars 2-?; loreals ?; temporals 2-?. Dorsal scale rows 21-21-19; ventrals 184; sub-caudals 48; total length ca. 464mm; tail length 75mm; tail length/total length ratio 0.161.

Top of head mostly black; white mottling present on supralabials, supraoculars, prefrontals, internasals, rostral, nasals, loreals, preoculars, and temporals. Frontal and postoculars on the left are entirely black; infralabials white with small amounts of black concentrated in the sutures; chin white with sparse amounts of black flecking.

The first white ring extends from the posterior 1/3 of the parietals to 2 1/2 scales back; length of remaining white rings 2 scales middorsally. White bands are all complete across the venter, although the black bands will sometimes encroach to form an imperfect alternating pattern. The number of white annuli on body 18; the number on the tail 5 with one more forming on the side. There is a very light amount of black flecking on all white rings with the least amount occurring on the two rings at each extremity.

Length of the first black ring 3 1/2 scales; middorsal length of remaining black rings 2-3 scales (mostly 2); lateral length of remaining black rings 1/2-1 scale (mostly 1). Number of black rings on body 35 (plus 1 directly above the vent); number of black rings on tail 7. The black rings never cross the red pigment middorsally, although a light suffusion of black pigment occurs on some red annuli.

Length of first red ring 8-10 scales; length of remaining red rings 3-5 1/2 scales middorsally. Number of red rings on body 18; number on tail 2.

The black annuli completely encircle the venter; in addition, the middle 3/5 of each ventral saddle is black. All of these black ventral saddles contain small white blotches or flecks of white. The tail has 3 large solid black annuli instead of saddles. The first 3 saddles on the anterior section of the specimen consist of a double row of black dots connecting the black annuli. This pattern gradually fills in to form the saddle pattern present along the remainder of the specimen.

Several of the features of this specimen suggest intergradation between *L. t. celaenops* and *L. t. annulata* (see Williams, 1978). These are:

1) The intermediate amount of black pigment on the head and chin.
2) The intermediate width of the black ventral saddles.
3) The progressive increase in the black ventral pigment from the throat to the first black ventral saddle.
4) The presence of white markings in the black ventral saddles.

In addition to these definitive intergradational characteristics, the scale counts and lengths of the body annuli fall within the range of variation of both subspecies.

We would like to thank Dr. Kenneth L. Williams for examining the data on this specimen and for his helpful comments.

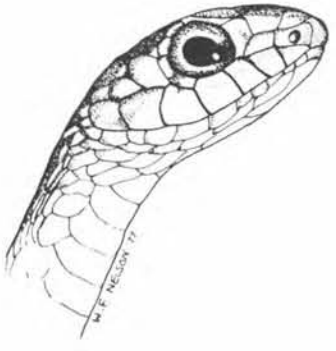
TWO *PHILODRYAS PATAGONIENSIS* FROM ONE EGG



On 29 October 1978, one of us (JCG) collected a 920 mm total length 'Parejera' *(Philodryas patagoniensis)* at Cerro Penitente, Departamento de Lavalleja, Uruguay. On 23 December, the snake laid 13 eggs. As this species lays eggs in *Acromyrmex* ant hills, the clutch was placed in a plastic bag with damp sawdust to provide the necessary humidity. Artificial heating was not provided. Most eggs were attacked by fungus, and 10 were removed. On 29 January 1979, one of the eggs was opened, and a well developed embryo was found. Its stage is similar to Zehr's (Copeia 1962:322-329) stage 36.

During the night of 20 February, one individual hatched (weight 2.50 g). This specimen is now (September 1979) 190 mm total length, and has eaten a diminute frog (*Pseudopaludicola falcipes*, Leptodactylidae) and a lizard's tail (*Pantodactylus schreibersii schreibersii*, Teiidae).

On 21 February, the remaining egg was opened, and two individuals joined by their umbilical cords to a common anexus were found. They were put in a clean plastic box with damp paper to provide humidity. One of the specimens has everted hemipenes. They are referred to Zehr's *(op. cit.)* stage 36. On 23 February, they lost their umbilical cords. The individuals refused to eat, and one of them was affected by an orbital abscess that gave the head a "salted" appearance.

On 6 March, one of the individuals died (133 mm total length, weight 1.45 g). The other snake was preserved on 11 March (144 mm total length, weight 1.40 g). They were deposited at the Departamento de Zoologia Vertebrados, Facultad de Humanidades y Ciencias (ZVC-R 2830 and 2831).

(Letter to Editor) EXPERIMENTAL CLEFT LIP AND PALATE IN *ALLIGATOR MISSISSIPPIENSIS*

Dean *et al.* (1980) provided a case report of bilateral cleft lip and palate in the progeny of a *Crotalus viridis viridis* Rafinesque. In this they highlighted the dearth of information on such anomalies in reptiles. It might therefore be of interest to point out that *Alligator mississippiensis* is being used as an experimental animal model in which to study developmental mechanisms in normal and abnormal palate formation (Ferguson, 1979a & b, 1981b, c, d, e, i). Basically, the advantages of the alligator system accrue from the fact that the crocodilians are the only animals which possess a true mammal-like secondary palate and which develop in an external egg. This means that all kinds of precise surgical and pharmacological experiments on early alligator embryos are possible, such experiments being impossible in the mammalian fetus because of its intra-uterine position and the deleterious effects of loss of amniotic fluid.

The alligator embryo is extremely sensitive to teratogenic chemicals introduced into the egg, and it is possible to induce various types of cleft lip and palate by injecting 0.01 mg of 5 Fluoro 2 Desoxyuridine (F.U.D.R.) dissolved in 0.1 ml of injectible water into the yolks of developing eggs at various times in incubation. Thus, the injections are performed on day 12 to induce cleft lip without cleft palate, on day 14 to induce cleft lip and palate, and on day 17 to induce cleft palate without cleft lip. *A fortiori* a technique has been evolved to grow normal alligator embryos in shell-less and semi shell-less culture (Ferguson, 1981a, e). By administering the teratogen at precise times in relation to several clearly defined embryonic stages in shell-less culture it is possible for the first time to reproducibly induce cleft lip on either the right or left sides (Ferguson, 1981e). By the same token, an injection of 0.01 mg of F.U.D.R. on day 10 blocks the migration of cranial neural crest cells into the lower jaw but not into the upper jaw, resulting in the development of an embryo with a normal palate but virtually no lower jaw or tongue. Using the combination of shell-less culture and this precise teratogenic schedule it is possible to study and film (using time lapse photography) the sequence of events in the development of the alligator palate. Ferguson (1981e) has reviewed the multiple advantages of the alligator as a model for experimental investigations of craniofacial embryology, whilst detailed histological and ultrastructural accounts of the structure and development of the alligator palate are available in Ferguson (1979a & b, 1981b-e). The pathogenesis of the induced anomalies appears to be related to a depression of the synthesis of hyaluronic acid, an extra-cellular glycosaminoglycan which normally provides a conducive milieu for neural crest cell migration into the palate. Numerous other defects, *e.g.* cyclopia, hydrocephalus, polydactyly and syndactyly can also be induced experimentally in the alligator.

Not only is the alligator model of enormous scientific and medical interest, but it has also had many spin-off applications in crocodilian farming and conservation. Thus, in order to evolve the shell-less culture technique it was necessary to perform an extensive investigation into the structure, chemical composition and mineral kinetics of the alligator eggshell and eggshell membrane (Ferguson, 1980, 1981a, f - h). This showed that normally the alligator eggshell is degraded by extrinsic bacteria present in the alligator nest and that this degradation increases the porosity of the eggshell and weakens it, causing it to crack, so facilitating hatching (Ferguson, 1981c, f - h). If alligator eggs are artificially incubated without nesting media, the hatchlings usually die either from respiratory defects or from an inability to break out of the abnormally tough eggshell due to a lack of extrinsic bacterial degradation of the eggshell. Other investigations have correlated the natural malformation rate in the wild with the age and diet of the female, whilst a tentative relationship between the temperature of egg incubation and the sex of the hatchling has been detected (Ferguson, 1981e & i).

TECHNIQUES

SURGICAL EXCISION OF A PERICLOACAL MASS FROM A KING SNAKE *(LAMPROPELTIS MEXICANA)*

Subject and History

The subject was an adult female king snake, *Lampropeltis mexicana*, that had been in captivity for four years. The animal was collected 21 June 1975 in Nuevo Leon, Mexico, and has been maintained in a group cage (60 x 60 x 50 cm) with another female and a male since August 1976. The cage provided photic and thermal regimens which were varied seasonally; summer maximum was 16:8 L:D, 28 ±4° C, and winter minimum (artificial hibernation) was 2:22 L:D, and 12 ±2° C. Lighting was with Vita-Lite fluorescent tubes (Duro-Test Corporation, Secaucus, N. J.). Water was available *ad libitum*. Each snake was offered 10 or more live juvenile mice per week during summer activity period; the snakes were not offered food during hibernation. Under this environmental regimen the subject mated and produced fertile clutches in 1977, 1978 and 1979.

When collected, the king snake had a 2 mm diameter palpable subcutaneous nodule lateral to the cloaca on the right side. The nodule regressed during 1976 but enlarged anteriorly after each yearly oviposition to approximately 3 cm long and 0.5 cm wide (Fig. 1). Prior to hibernation in November 1979, feeding and defecation were abnormal, and general activity was reduced. Surgery was performed during hibernation because the subject could be expected to heal before the spring reproductive period.

Surgery and Postoperative Care

The snake was anesthetized with Brevitol Sodium (1.5 mg/kg BW) (Wang, Kubie, and Halpern 1977) injected intraperitoneally. The skin was prepared with 70% ethanol and an incision approximately 2 cm long was made between the first and second scale rows dorsal to the ventral scutes. The incision was begun 1.5 cm anterior to the cloaca and continued posteriorly. Care was taken to cut between and not through individual scales. The skin was gently teased away from the underlying muscle and ribs. This exposed two ovoid masses approximately 1.25 x 0.5 cm and 1.0 x 0.5 cm, and several smaller ellipsoid masses grading to less than .1 cm long. These masses were soft to palpation and were covered with an elastic envelope. They were poorly vascularized and contained a pale yellowish, slightly granular material. All but one mass was easily removed by simply teasing away the surrounding tissue with curved serrated forceps. The last mass was posterior and lateral to the cloaca and was connected to a highly elastic conical portion of tissue whose tip was attached deeply posterior to the cloaca. The mass and tissue were excised by cutting the conical tissue as close as possible to its tip. The entire procedure resulted in minimal hemorrhage. The excision site was subsequently irrigated several times with sterile reptilian Ringer's saline. Finally, the incision was closed using 6-0 Prolene polypropylene suture (Ethicon, Somerville, N. J.) in a simple interrupted pattern between each scale. Past experiences with surgery on snakes have shown that cutting and suturing between scales facilitates healing, alleviates problems with ecdysis, and reduces cosmetic damage. No antibiotic therapy was given.

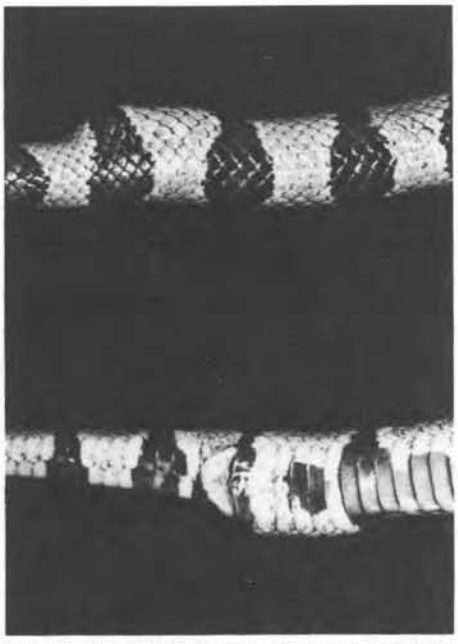

Fig. 1. Appearance of the nodule prior to surgery, dorsal (L) and ventral (R) aspects.

The subject was placed in an isolation cage which provided a 12:12 L:D photic cycle and a temperature of 18° C (± 2° C). Recovery from anesthesia was slow, requiring approximately 48 hours. The wound drained serous fluid for 24 hours and was edematous for 72 hours. Healing appeared complete after one week, at which time the subject was returned to hibernation in the group cage. The photic cycle was changed to 10:14 L:D on 21 March 1980 and the subject became active within a few days. The first observed feeding was 4 April. Copulation was observed 7 and 21 May. The sutures were shed with the skin on 8 June (Fig. 2). Oviposition of 11 eggs was on 16 June.

Histology

The masses (Fig. 3) were placed in neutral buffered 10% formalin while the conical portion of tissue was placed in Bouins fixative. The tissues were embedded in paraffin, sectioned at 7 μm and stained with hematoxylin and eosin. Histologic examination of tissue sections revealed that the masses were composed of cystic structures with an epithelial lining. The lumens contained eosinophilic cellular debris with cholesterol clefts and occasional bacterial colonies. Examination of sections of the conical tissue revealed it to be a folded structure containing a lumen lined by a thick stratified squamous epithelium. The epithelium of the gland was multifocally infiltrated with heterophils and the

Fig. 2. Sutures present in the shed skin.

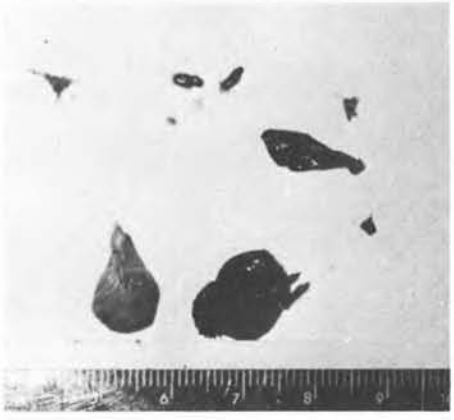

Fig. 3. Masses removed in the surgical procedure.

lumen contained cellular debris and numerous bacteria. The surrounding subcutaneous tissues contained occasional foci of mixed inflammatory cells. Histologically the folded conical structure was consistent with being a cloacal gland. The pathologic changes probably resulted from a bacterial infection or injury of the right cloacal gland. The lumen of the gland was occluded and had apparently ruptured and healed with the lumen opening into the subcutaneous space. Glandular products and debris of the infection then formed the masses. The relation of the symptoms to reproductive periods may have resulted from either a lowered resistance to the chronic infection during pregnancy, or pregnancy-related activity of the gland.

A NEW TECHNIQUE FOR RECOGNITION OF SNAKES

Being able to recognize individual specimens in zoo collections is important for several reasons. Among these are: the data that can be provided by the particular individual with respect to its species; to insure proper care and maintenance of the specimen; and, simply, to keep track of the individual from the time of its arrival until the time of departure.

In snakes, particularly those species with patterns, it has been traditional to locate some pattern irregularity and to verbally describe or make a sketch of it, record the shape and location of pre-existing scars, clip certain scales, or use photographs for the purpose of identifying individuals.

The Ellen Trout Zoo is currently using a unique method for this purpose that employs portions of the exuvia. This technique, developed by the zoo's reptile and bird technicians, consists of locating the particular pattern irregularity, scar or other distinctive characteristic on the exuvia and removing this portion of the skin. After it has sufficiently dried, the portion of the exuvia is split in an appropriate place so that the identifying mark may be displayed in the same fashion that it can be observed on the living snake. The segment is then placed on the specimen's data card and covered with clear, adhesive plastic, thereby preserving it for future reference.

This method has proven useful to us for several reasons: it is more accurate than a description or drawing, especially when considering two, or more, individuals of the same species that may have similar patterns; it does not involve mutilation of any sort; and it is cheaper and does not require the time and equipment necessary to photograph specimens.

Useful as it is, this method of distinguishing individuals is not without its drawbacks. It is most useful with species that have definite patterns or on individuals with distinct scars. Hence, it is not as useful with species that are virtually unicolor, or individuals without scars, or in those species that exuviate in flakes. In metachrotic species, the specimen samples are changed after the color change has been completed.

Acknowledgment

I would like to acknowledge J. Kevin Steltzlen and B. R. Smith for their ingenuity and imagination in developing this technique.

LEGISLATIVE ALERT

Once again there is a Congressional move (i.e., Chafee in the Senate, Breaux in the House) to introduce legislation that will "tighten" controls on illegally taken fish and wildlife. The main points of S. 736 and H.R. 1638 are as follows: 1) consolidation of the Lacey and Black Bass Acts to cover all species of fish and wildlife that are subject to federal, state, and/or foreign conservation laws; 2) extend protection to plants that are subject to state conservation laws and provide federal assistance to states with plant conservation laws; 3) increase the maximum civil penalty to $10,000 (current maxima are $5,000 under Lacey Act and $200 under Black Bass); 4) increase the maximum criminal penalties to $20,000 and 5 years imprisonment (current maxima are $10,000 and 1 year under Lacey Act, and $200 and 3 months under Black Bass); 5) defines the criminal culpability standard — the government will be required to prove only that a defendant had knowledge of the underlying conservation statute, but will **not** be required to prove that the person also had knowledge of the Lacey Act; 6) provides a "relaxation" of labelling provisions currently in effect for shipping fish and wildlife, but allows the Secretaries of Interior and Commerce to promulgate joint regulations **re:** labelling which are consonant with industrial practices and which satisfy enforcement; and 7) adds Native American regulations to the Lacey Act to ensure that fish and wildlife regulations applicable to Native American reservations will be subject to federal enforcement.

Copies of the proposed legislation are available from the following offices: S.736 — Committee on Environment and Public Works (Sen. John H. Chafee-R, RI), Dirksen Senate Office Bldg., Washington, D.C. 20510; H.R. 1638 — Committee on Merchant Marine & Fisheries (Rep. John B. Breaux-D, LA), Rayburn House Office Bldg., Washington, D.C. 20515.

FUNDING OPPORTUNITY

AWARDS FOR STUDY AT ANSP

The Academy of Natural Sciences of Philadelphia, through its Jessup and McHenry funds, makes available each year a limited number of awards to support students pursuing natural history studies at the Academy. These awards are primarily intended to assist predoctoral and immediate postdoctoral students. Awards usually include a stipend to help defray living expenses, and support for travel to and from the Academy. Application deadlines are 1 April and 1 October each year. Further information may be obtained by writing to: Chairman, Jessup-McHenry Award Committee, Academy of Natural Sciences of Philadelphia, 19th and the Parkway, Philadelphia, Pennsylvania 19103. ●

BOOK REVIEWS

A. M. Alekperov **The amphibians and reptilians of Azerbaidjan** (in Russian) Baker, 1978, 264 pp. Illustrated.

This monograph is the author's 1957 doctoral dissertation but contains some new observations since then and new literature about the herpeto-fauna of Azerbaidjan—part of the Caucasian area of the U.S.S.R. The book contains detailed chapters about the history of herpetological research and collections in this area and descriptions of known species of Azerbaidjan. The systematic and taxonomic problems are not discussed in detail and discuss only information about distribution and ecology of species in Azerbaidjan. The chapter about general problems of ecology of amphibians and reptilians contains classifications of herpeto-fauna of various biotopes for forests, mountains, and arid biotopes. It also presents some of the author's observations about anthropological factors affecting herpeto-fauna (modern human's activity, agriculture, construction, industry and herpeto-fauna in these cultural landscapes). However, these observations would benefit from more detail and greater studying of ecology of some species. The book contains a chapter about the history of Azerbaidjan herpeto-fauna and its origins that includes some new physical analysis and description of herpeto-fauna of the East Caucasian and High Mountain districts, the Asiatic district, and detailed description of specialized forms in these regions. It is especially of interest to herpetologists specializing in this region. But, the maps of species areas in Azerbaidjan may be useful for any collectors and amateurs.

The chapter about the practical importance of amphibians and reptilians includes some Azerbaidjan observations: feeding by harmful insects, turtles in this area may be harmful as eaters of useful fishes and vegetables and as reservoirs of infection (also some other species of herps). The author states that lizards may be used as laboratory animals as are frogs. The materials about epidemiology of snake bite is very interesting. Snakes bite up to 25% of domestic animals and 200 humans yearly (47% of these are 16-50 years of age; 90-95% bites are to feet of agricultural workers, but the lethality is only 1.3%). According to the author, venomous snakes also need protection as venom producers for medical research. In Azerbaidjan, there are snake farms with 2000 snakes that give up to 2 kg of venom yearly. As a regional monograph, this book is useful for any students, animal lovers, or zoologists. But only a few copies are available, as limited circulation is due to a very small press run. The book gives scientific names and native names of species, but no foreign names (including English) are used.

V. Ischenko **The dynamical polymorphisms of brown frogs in fauna of U.S.S.R.** Moscow, Science Publication 1978, 148 pp. with illustrations (in Russian).

This book discusses the ecological structure of populations in various species of brown frogs, and their genetic structure including problems of evolution, management and mathematical models of these processes. Also included is some material about ecology of various populations. The author's work is based on collection and study of a large quantity of frogs: 19,000 *Rana arvalis*, 493 *Rana temporaria*, 558 *Rana cheusinensis*, 4,495 *Rana macrocnemis*, 5,215 *R. camerans*, 275 *R. dalmatina*, 412 *R. amurensis*. The author presents his concepts of the population biology of these species, and discusses the difference in characters within species between populations. The work incorporates early research of the well known Soviet ecologist S. Shwarz, and includes chapters on: Description of anuran polymorphics, Description of brown frogs, Structure of species and populations, Specification of morphs and abiotic factors in population existence and Experimental management of populations. This book is for ecologists, zoologists and herpetologists, too, but not for amateurs as it is too technical. Only a few copies of this book are available; it is out of print and rare in the trade.

NOTE: All cited Russian literature (including yearly reviews) are listed in the Russian language version only. Not printed in English version.

Common Snakes of South East Asia and Hong Kong, by Frank Reitinger. Heinemann Educational Books Ltd.: Hong Kong 1978.

Ditmars' observation that snakes are nowhere more common than in stateside fields and forests holds true in the small British colony of Hong Kong. While the coastal region is heavily urbanized, the inland hills of Hong Kong are uninhabited and overgrown to the extent the slope and shallow soil permit. Daytime field trips by biology classes that overturn any stones within sight consistently fail to yield reptiles.

Dr. Reitinger's success in collecting a wide range of snakes from this area rests with the discovery that the water catchment system acts as an entrapment. Hong Kong relies heavily on rainfall to supply water for over four million people clustered in the county-sized colony. Typhoon rains that convert mountainsides to temporary waterfalls are intercepted by concrete ditches that channel the torrents around the mountains to inland reservoirs. These channels, or water catchments, are often up to twenty feet wide and deep, and run many miles with intermittent tunnels through ridge crests. Snakes swept downhill into these trenches during heavy seasonal rains are often unable to scale the vertical concrete walls. Eventually they make their way to the tunnelled sections and thrive on the abundance of frogs and invertebrates. Weekly nighttime hunts along the largest catchments has permitted Dr. Reitinger to sample the wide range of snakes sparingly found in the area, including several new records, in the brief six years he has resided in the colony.

Ironically, a description of this entrapment, which has provided the bulk of the author's specimens, has been intentionally omitted from this book. In a culture where snakes are heavily utilized for both food and medicine, such a disclosure would result in a regular gleaning of the catchments.

While this paperback handbook is designed to appeal to the tourist market, it is a welcome text to the regional biology teacher interested in conveying the life histories of non-venomous as well as poisonous snakes. It may also prove to be a handy occasional reference for herpetologists worldwide.

The first thirty pages cover the general biology of snakes in a lively style. The middle half of the text systematically outlines information on each of fifty species of snakes: scientific name, description, food and habitat, breeding and field notes. Although the field observations are narrated, the descriptive segments are in telegraph style and restrict the whole section to reference and identification work.

The keys to families, genera and species are well-organized and clear, and a complete glossary that assumes no previous experience in the field is available. Therefore, local teachers and students alike can approximate the identity of their specimens. Dr. Reitinger has reared snakes both in Hong Kong and in Vietnam, where he served as a medical officer, and he includes observations on rearing captive snakes. An index, essential to a reference book, is present.

Reflecting Dr. Reitinger's medical training, the general account of venoms, snakebite and particulars for each venomous species is more complete than in most regional guidebooks.

Photos are excellent, and the author makes an unusually strong effort to recognize the contributions of his photographer in the section headings, author line and copyright.

The author also makes a strong pitch for conservation of snakes within the colony. His nine recommendations on reptiles and general conservation reflect years of dealing with regional dealers, exporters and colonial law. Some comments on conservation rather ramble, with mathematical examples often straining the points (Rats are bred to two trillion in ten generations. And many will not react favorably to "coldly" valuing a human life at US $10,000 to make an economic comparison).

Recognizing that the book will primarily be marketed with tourists, the discerning reader and the professional herpetologist may expect more.

—A co-listing of snake names in Chinese characters would have been handy for individuals trying to compare this modern information with older accounts of uncertain species.

—Medical jargon abounds (Necrosis, vasodilation, etc.) but the general reader's vocabulary will readily expand by reference to the glossary.

—Range maps in the text would be superior to the regional distribution chart that checks off countries of residence (a snake is found in the Philippines . . . all of the islands?).

—The bibliography is diminuitive . . . ten citations of mostly general and old texts with western authors. Since not all of the citations are still in print, it is not evident why the list is not more extensive, including journal articles. Not only herpetologists, but general readers converted to an amateur interest would appreciate the leads to further literature.

—Line drawings of head scale pattern for eighteen selected snakes are clustered in the back of the book. All lack labels of distinguishing features, lack a reference scale (the largest drawing is of the minute blind snake) and will receive little perusal since each is divorced from its description in the text.

The lack of a justified right margin and the seclusion of the magnificent color plates to one final signature at the end of the book is a necessary evil, acknowledging the high cost of books in Hong Kong, and thankful that this small paperback will not be too expensive.

An ultimate sin has been committed by the publisher, however. The binding readily comes apart . . . a critical blow to a text that could serve a heavy reference function throughout Hong Kong schools.

For the herpetologist, no other book covers the non-venomous snakes of this area for modern times. Should you buy a copy, have it rebound.

(Available from: Heinemann Educational Books (Asia) Ltd., K.P.O. Box 96086, Tsim Sha Tsui Post Office, Kowloon, Hong Kong, 1978. Current price is US $5.00. Packing and postage for surface mail is about US $.65 additional and requires a minimum of two months delivery time. Air mail postage would run about US $2.50.)

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

FIRST SUCCESSFUL CAPTIVE PROPAGATION OF SCHNEIDER'S SMOOTH-FRONTED CAIMAN, *PALEOSUCHUS TRIGONATUS*

EDITOR'S NOTE

Through a baffling, infuriating and most unfortunate set of circumstances, this article was hopelessly scrambled in the last issue. We apologize to Mr. Jardine and to readers, and here reprint the entire article in correct format.

INTRODUCTION

Of all the crocodilians, the genus *Paleosuchus* is perhaps the least known. Neither of the two species assigned to the genus, *P. palpebrosus* (Cuvier, 1807) and *P. trigonatus* (Schneider, 1801) is well known. Specimens of the genus are found in South America, in swift moving, often turbulent waters of the tropical rain forest. The southernmost locality appears to be Bahia; to the west it is found from Rio Abuna, Bolivia, and from the Huallaga and Ucayali in Peru. In the north, it is known from the Rios Sansa and Ocoa, Colombia, and as far north as Angostura on the Rio Orinoco, Venezuela. To the east, it is found mainly in Guiana, Surinam and Mexiana Island. Both species apparently occur together not only over most of the Amazon and Orinoco basins, but even as far as extreme eastern Brazil (Medem, 1958).

Although their hide, because of its osteoderm, is of little value, they are hunted by natives for use as food, and such activity very likely has reduced their range since the above distribution was recorded. Medem (1958) noted that individuals, even juveniles, were always solitary. It is known that they hide most of the day and hunt in late evening (Medem, 1958). There are a few *Paleosuchus* in captivity. In a survey of American zoos, only 15 animals were located: 5 males, 3 females and 7 of undetermined sex (Dobbs & King, 1975). Information on reproduction in the genus is incomplete. Only recently has work been done on *P. palpebrosus* (Medem, 1972), resulting in successful propagation, and only preliminary reproductive data from eggs found in the wild are available for *P. trigonatus* (Dixon & Soini, 1975). Here I report the first successful captive propagation of *Paleosuchus trigonatus*.

MATERIALS AND METHODS

The Zoological Society of Cincinnati obtained a juvenile male *P. trigonatus* in March, 1966, and a juvenile female in May, 1967. Both were purchased from the same individual but no locality data are available. Eventually they were placed in a circular pool, with a concrete island, located in the Reptile House lobby. The pool housed many other species of crocodilians of varying ages and sizes. Breeding was first observed early in 1975. Eggs were laid on the night of 24 March, 1975, on the

island. Unfortunately they rolled into the water and all were broken but one, which proved to be infertile. It was then decided to concentrate efforts with these *Paleosuchus* and isolate them in a separate enclosure, which was provided in September, 1975.

The new enclosure is a large indoor exhibit located at one end of the Bird House. The area is densely vegetated with live plants and covered with a large skylight which provides a natural photo-period. The enclosure consists of a pool 3.35 x 3.66 x 1.22 m in depth, rising at a gradual incline to a land area of 3.66 x 2.44 m. The water temperature ranged from 21° C in winter to over 27° C in summer. The air temperature was about 21° C in winter, with the summer temperature determined largely by the outside natural conditions. The area was readily open to the public, with only a railing fence as separation. Prior to isolation in the new enclosure, the female specimen was 1.22 m in length and the male specimen was quite large at just over 1.83 m. Their diet consisted of blue fish, horse meat, and rats as supplements. They were fed twice a week in summer and offered feed every 10 days in winter, but the animals showed little interest in feeding during the winter. The move to the new enclosure proved to be quite traumatic for the two caiman and resulted in both animals going off feed for nearly one year. No signs of breeding were noted, but early in 1979 eggs were produced. These eggs were removed and incubated artificially. They were placed in a styrofoam container (180 mm deep and 415 mm square) and covered with peat moss. The eggs were buried in the center, and the container was covered with a sheet of glass. Incubation temperature fluctuated from 29°-31° C and from 92-100% relative humidity. Periodically the peat moss was sprayed with water. Temperature and humidity of the peat moss were monitored twice daily (early morning and late afternoon) and a visual check of the eggs was made weekly. The artificial incubation resulted in the hatching of six caiman.

RESULTS AND DISCUSSION

Seventeen eggs were observed on 8 January, 1979, at 0200. The eggs had apparently rolled into the water, but could not be retrieved until 0700. Water temperature upon removal was 15° C. When removed, the eggs were covered with a clear gelatinous substance. Because it was unknown if the five hours in water had ruined the eggs, one egg was opened after 28 days. It was found to be fertile and there was visible body development (eyes and beginnings of leg protrusions and a visible heart beat).

Since the incubation period for *P. palpebrosus* is known to be 90-92 days (Medem, 1972), the eggs were candled on 4 April, after 94 days of incubation, and of the 16 eggs remaining, 7 were found to be fertile. All eggs were uniform in size and weight with a rough calciferous surface (Fig. 1). With no signs of hatching after 102 days, another egg was opened on 10 April. This particular egg was selected because it had a small crack in one end of the shell, with a clear substance containing blood vessels protruding. The egg

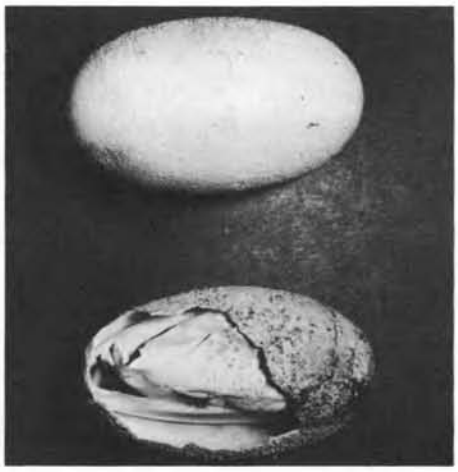

Figure 1. Unhatched and hatched egg; note inner membrane separated from outer shell in hatched egg. Janet Ross, Zoological Society of Cincinnati.

Figure 2. Young caiman after entering water. Fred Straub, Cincinnati Enquirer.

contained a live, alert animal thought to be 1-3 weeks premature. The animal measured 180 mm and was fully developed except for a small amount of scale area around the yolk sack attachment area. The young caiman, still in the lower half of the egg, was placed in a small covered container with a moist paper towel to retard moisture loss. It lived for 25 hours, during which time it remained alert and defensive but made no effort to free itself from the egg sack. The animal was preserved (CVG-A. 38089).

Although incubation had gone well beyond the expected time, it was decided to let the remaining eggs run their full course. Beginning 1 May, 112 days after oviposition, the eggs were uncovered daily and a grunt call was made along with a gentle movement of the eggs to simulate the actions of the adult female caiman (Medem, 1972). The peat moss covering was sprayed with water each time to replace any moisture loss and maintain the desired humidity level. On 3 May, after 114 days of incubation, as the eggs were moved, a crack developed in one. Because the crack neither extended nor widened and no return call came from the egg, it was covered again and left for the night. The next morning (14 hours later) the cracked egg looked the same. However, after the movement of the egg and calling procedure was repeated, in a single motion, the young caiman propelled itself headfirst out of the egg. The hatchling was covered with a thin clear mucus, like that noted by Medem (1972) for *P. palpebrosus*. Since Medem (1972) found that a hatchling *P. palpebrosus* placed directly into water died, the young caiman was placed in a tank containing a mixture of moistened sheet moss and peat moss and a piece of cork bark under which it could hide. The caiman was kept in this container for 24 hours, in keeping with the notion that hatchlings in the wild spend from 24-48 hours in debris and dry leaves to allow the mucus to dry completely and to allow a toughening of the hide to occur. This procedure was repeated with the remaining hatchlings.

TABLE 1. Weight and Length Measurement for Six Hatchling *Paleosuchus trigonatus* on 9 May, 1979

	Length (mm)		Weight (g)
	Snout-Vent	Tail	
1.	112.0	110.0	45.5
2.	111.0	110.0	46.2
3.	111.0	96.0	46.5
4.	110.0	112.0	43.5
5.	110.0	110.0	44.0
6.	109.0	112.0	47.5

By 7 May, 118 days after the eggs were laid, six caiman had hatched (Table 1). Three responded to the call and egg movement procedure and immediately emerged; one came out at night on its own, and two cracked their eggs and returned a call but remained in the egg up to 48 hours before completely emerging. After the 24-hour drying-out period, the young were placed in a 30-gallon aquarium with one end elevated about three inches. The higher end contained moistened peat and sheet moss mixture; the lower end contained water and a cork bark shelter. All hatchlings remained on the elevated moss area, often digging under moss for seclusion, and then entered the water during the dark evening hours. They continued their seclusion under the bark and seldom left the water (Fig. 2).

The adult female caiman is known to aid in the cracking of the shell if the hatchlings cannot get out on their own (Medem, 1971). In the present case, the hatchlings readily cracked the eggs themselves. Actually, at the point of hatching, the hard, brittle outer shell seemed to be visibly weakened with the hairline cracks and fell away easily from the thick inner membrane as the young emerged. Of the six hatchlings, one developed an abdominal problem and died two weeks after birth. The animal was preserved (CVG-A. 38131). The remaining five were alert and healthy in appearance and were offered a first food of crickets (dusted with vitamins) after 14 days. When these were readily accepted, live gold

fish and live juvenile mice were added to the diet and kept available to the caiman at all times. As of 19 October, 1979, all five are doing well and growing rapidly.

Acknowledgments

I would like to thank Edward Maruska, Dr. Kraig Adler, Dr. Leslie Garrick, and Dr. Richard Davis for reviewing this manuscript, and those others who gave helpful comments. The two dead embryos (CVG-A. 38089, CVG-A. 38131) are in the Cincinnati Zoo's preserved collection.

BREEDING AND REARING OF CAPTIVE SOLOMON ISLAND GROUND BOAS, *Candoia carinata paulseni*

This paper concerns captive breeding and rearing of the Solomon Island Ground Boa, *Candoia carinata paulseni,* in four successive years. Prior descriptions of the reproductive biology of this species are scarce. *International Zoo Yearbook* (1975) mentions two litters born in 1973, one in Bristol, England, and the other at the Institute for Herpetological Research in Redwood City, California. Murphy *et al.* (1978) commented on the use of vestigial limbs in the courtship of *Candoia bibroni,* and reported the birth of 64 still-born *Candoia carinata* in February 1974. No breeding information was given.

Materials and Methods

Two female *Candoia carinata paulseni* (*A* and *B*, total lengths 82 cm and 58 cm, respectively) were obtained in June 1973. That September a 57 cm male was received. Two additional females (*C* and *D*, total lengths of 60 cm and 105 cm, respectively) were available in 1977 on breeding loan. Sexes were determined by the presence (males) or absence (females) of spurs. No historical data were available for any of the specimens. During the study all snakes were maintained under indoor conditions in Tampa, Florida (27°58'N, 82° 32'W).

Snakes were housed in two glass-fronted wooden cages (90 x 52 x 62 cm) with Sani-Cel® (ground, dehydrated corn husk) provided for bedding. Except during the winter, cage temperature and humidity were dependent upon natural environmental conditions; from December through February the room was heated to maintain a minimum temperature of 14° C; the maximum was 21° C. Presence of a large window near the cage fronts provided a natural light cycle. Adults were offered mice and young rats weekly. Young were fed one to two weeks after birth on small *Anolis sagrei* or day-old pinkie mice. Anoles and pinkie mice were offered every ten days thereafter, except to Litter 6 which was offered food every five days.

Observations

First Breeding Season

From the time of acquisition the male was housed alternately with females *A* and *B*. During this period I observed no courtship or copulatory behavior. Early in March of 1975, the male was caged alone. On 19 April 1975, the male (62 cm) was returned to the cage with the two females (67 cm and 92 cm). No signs of courtship or mating were observed. On 20 April 1975, at 1400 h, I observed copulation for the first time between the male and female *A*. The tails were entwined vent to vent and the snakes were motionless. Breeding in this manner occurred periodically for approximately four weeks, with the longest duration of continuous copulation lasting about four hours. The last date of observed mating was 20 May 1975. Copulation was never noted between the male and smaller female *B*. The specimens were not fed during this period. By the end of May, all of the animals, still housed together, were again feeding well. By mid-October female *A* appeared heavier than would be warranted from the amount of food ingested and was assumed to be gravid.

On 2 November 1975, at 0130 h, eight neonates were noted in the cage, some crawling around and some within amniotic membranes. At this time I observed two more births; each took approximately three minutes with a 15 minute interval. By 1000 h, the entire brood of 27 young had appeared. All were active, some had undergone their initial shed, and all shed by the second day. The cloacal region of each neonate was examined for the presence or absence of spurs. Information concerning the sex and size of young is presented in Table 1. All young possessed one of two distinct dorsal patterns on a grayish ground color. One dorsal pattern consisted of a continuous dark gray dorsal stripe resembling that of the adult male, the other a lighter gray broken stripe resembling that of the adult female. These patterns were not sexually dimorphic.

Second Breeding Season

The second brood was produced by the smaller female *B*. All three snakes (male, females *A* and *B*) were housed together throughout the spring and summer months of 1976. Although I observed no courtship or copulation, it likely occurred during the

months of June through August in my absence. By December female *B* appeared gravid.

On 1 January 1977, at 1430 h, female *B* gave birth to 19 young; 15 were alive, two perfectly formed but stillborn, and two deformed and stillborn. Shedding occurred two to four days after birth. Sizes and sex ratios are given in Table 1.

Third Breeding Season

In April 1977, the male was introduced to females *A* and *B* after a three month separation. Within two hours copulation occurred with female *A*. One week later the male was transferred to the cage containing females *C* and *D*. During the next two weeks the male copulated with each of these females. The male was then reintroduced to females *A* and *B* and copulation occurred with female *A*. A few days later the male was placed with females *C* and *D*, and copulation occurred with each of these females. By the end of May all mating activity had ceased.

On 6 December 1977, female *A* gave birth to 22 young of which five were stillborn. Female *A* died on 10 March, three months after giving birth. She was not autopsied.

On 22 December 1977, female *C* gave birth to 16 neonates, 11 of which were stillborn. On 5 January 1978, female *D* gave birth to 33 perfectly formed stillborns.

Fourth Breeding Season

The male was introduced to female *B* in April 1978, and copulation occurred within 30 minutes. After one week the male was removed and placed with females *C* and *D*. Copulation was not observed and after two weeks the male was returned to female *B*. Again, copulation began immediately with female *B* and recurred sporadically over the next two weeks, after which time the male was reintroduced to females *C* and *D*. Once again no copulation was observed and after two weeks, in early June, the male was placed with female *B*. No further copulation was observed.

On 10 November 1978, female *B* gave birth to 24 live young.

Summary of Breeding Observations

The preceding observations indicate that captive *Candoia carinata paulseni* may follow a fixed reproductive pattern. Females seem to be receptive for a period of about two months (April — May), during which time copulation occurs intermittently. Unlike *Candoia bibroni* (Murphy *et al.*, 1978), *Candoia carinata paulseni* do not appear to use the pelvic spurs during courtship. Furthermore, females appear to be receptive only every other breeding season. Huff (1978) mentions that many, if not all, of the insular forms of *Epicrates* follow this biennial reproductive cycle.

The large proportion of stillborns in Litters 4 and 5 may have been caused by either of two factors: 1) the very harsh winter (although the temperature never dropped below 14° C, it may have remained low for too long a period of time), or 2) insufficient time for the females to adjust to the new environment, since they had been placed in the collection two months prior to copulation.

Behavior of Young

All young *Candoia* specimens resembled the adults in coloration and pattern. Their light gray color tends to become more vivid and distinct with age, and at three years they possess the adult coloration.

From my observations, the young are hardy, feed well from birth, and adapt easily to captivity. Growth data are summarized in Table 2.

Two protective traits not seen in the adults were noted in newborn snakes. When disturbed, the young feigned death (appearing stiff and lifeless) or, less frequently, balled up (tucking head into middle of coils). This balling behavior observed in the young also has been seen in adult *Candoia aspera* (Bustard, 1969).

Acknowledgments

My sincerest thanks go to Bob Wallen who loaned me specimens, to Sandy Russo who typed the early drafts, to Karyn Wallace who typed the manuscript, to Paul Halibrin, Steve Godley and Dr. Roy McDiarmid for reading early drafts. A special thanks goes to Dr. Dale Jackson for guidance and critically reading the manuscript.

REPRODUCTION OF *LAMPROPELTIS TRIANGULUM ELAPSOIDES* FROM ONSLOW COUNTY, NORTH CAROLINA

There are few reports of reproduction of the scarlet kingsnake *(Lampropeltis triangulum elapsoides)* in the literature. Williams (1978) summarized the known data, citing accounts from North Carolina (Palmer: 1961, *in litt.*), Mississippi (Allen, 1932), and Duval County, Florida (Groves and Sachs, 1973). Reproductive data from a Dade County, Florida specimen has also been published (Groves and Assetto, 1976) (Table 1). This report deals with the oviposition, incubation, and hatching of a clutch of eggs from a gravid female from North Carolina.

On 30 April 1979, a female *L. t. elapsoides* (total length 492 mm, snout-vent length 421 mm) was collected under a rusty lawnmower near Holly Ridge, Onslow County, North Carolina (Barten, 1979). She was placed in a ten gallon aquarium with newspaper substrate, a piece of cork bark, and a water dish. On 4, 8, and 27 May 1979, she ate frozen-thawed newborn mice. She shed on 25 May 1979. A plastic shoe box was filled with sawdust that had been collected from an abandoned logging camp near the female's capture site. A 2 cm access hole was cut in one side, and the box was placed in the aquarium with the female. She was observed to spend much time burrowing through the sawdust.

Fig. 1. Hatching scarlet kingsnake, *Lampropeltis triangulum elapsoides.*

On three occasions during the week of 7-14 May 1979, the female was placed with a male *L. t. elapsoides* that had been captured at the same site five years earlier. The male was observed to court the female, who fled whenever mounting was attempted. Actual copulation was not observed. On 14 May 1979, the caudal one-third of the female was observed to be quite distended. The snake was diagnosed gravid and was separated from the male.

At 0700 hours on 4 June 1979, five eggs were discovered in the sawdust. They were presumed to have been deposited the previous evening, just 7 days after the female's last meal. The eggs were adhered together in a cluster. Measurements with a vernier caliper were 24.8-26.2 x 13.5-14.0 mm (mean 25.2 x 13.8 mm). Incubation was accomplished by removing the female from the aquarium and leaving the eggs in place in the sawdust. The temperature ranged from 23-28° C during the day and 20-23° C at night.

On 5-6 August 1979, after 63 days, the eggs hatched. The 2 male and 3 female hatchlings ranged in size from 178-188 mm (mean 182.6 mm). The natal skins were shed on 11-13 August 1979. All five hatchlings ate metallic skinks *(Leiolopisma metallicum)* and ground skinks *(Leiolopisma laterale)*, both alive and frozen-thawed. They refused newborn brown snakes *(Storeria dekayi)*, small anoles *(Anolis carolinensis)*, and western chorus frogs *(Pseudacris triseriata)*.

TABLE 1. Reproductive Data for the Scarlet King Snake *(Lampropeltis triangulum elapsoides).*

Copulation	29 May	Palmer (*in litt.*)
Gravid Female Collected	30 April	Barten
	May	Groves and Sachs (1973)
	June	Allen (1932)
	September	Groves and Assetto (1976)
Oviposition	3 June	Barten
	3 June (2 clutches)	Groves and Sachs (1973)
	4 July	Palmer (*in litt.*)
	8 October	Groves and Assetto (1976)
Egg Size	24.8-26.2 x 13.5-14.0 mm	Barten
	27.7 x 10.8 mm	Palmer (1961)
	21.2-28.4 x 9.4-11.7 mm	Groves and Sachs (1973)
	23.2-30.2 x 9.6-11.8 mm	Groves and Assetto (1976)
Clutch Size	3, 4, and 6 eggs	Palmer (1961), (*in litt.*)
	5 eggs	Groves and Assetto (1976)
	5 eggs	Barten
	4 and 7 eggs	Groves and Sachs (1973)
Hatching	5-6 August	Barten
	7 and 9 August (2 clutches)	Groves and Sachs (1973)
	23-24 August	Palmer (1961)
	11 September	Palmer (*in litt.*)
	12 December (dead embryo removed from egg)	Groves and Assetto (1976)
Measurements of Neonates	146 and 159 mm	Palmer (1961)
	138.0-203.4 mm	Groves and Sachs (1973)
	150 mm	Groves and Assetto (1976)
	178-188 mm	Barten

Acknowledgments

Thanks to Jerry Reynolds for collecting and donating the female *L. t. elapsoides.*

NEWSNOTES

EUROPEAN HERP SYMPOSIUM PROCEEDINGS

The titles below (plus numerous others omitted for brevity) were presented at the 1980 Symposium; the proceedings volume may be obtained by writing to:

John Coburn
Cotswold Wild Life Park
Burford, Oxon. OX8 4JW
England
Telephone: Burford 3006

Titles:

Mr. John Coborn (Symposium Organiser): "Introductory Speech."

Prof. H. S. R. Glaser (Giessen, W. Germany): "The programmable environmental control system for the Amphibian and Reptile exhibit at the Roeding Park Zoo, Fresno, California."

Dr. T. Hagström (Göteborg, Sweden): "Reproductive strategy and success of frogs and newts in waters acidified by atmospheric pollution."

Dr. T. Beebee (BHS Conservation Committee): "Ecology and conservation of the Natterjack Toad, *Bufo calamita*, in Britain."

Dr. D. Dolmen (Trondheim, Norway): "Distribution and habitat of the common newt *Triturus vulgaris* and the warty newt, *T. cristatus* in Norway."

Dr. K. Klemmer (Frankfurt, BRD): "Amphibian conservation in Hessen - Bundesrepublik Deutschland."

Dr. I. Spellerberg and
Mrs. Susan House (Southampton): "Problems faced by oviparous reptiles in temperate climates." ●

KANSAS ACADEMY OF SCIENCE

HAVE YOU SEEN THE FOLLOWING TITLES?

Two new species of *Eleutherodactylus* (Anura: Leptodactylidae) from the Peruvian Andes.

Reptiles collected from the west coast of the Cape Province, Republic of South Africa.

A field study of the prairie king snake *(Lampropeltis calligaster).*

A new rattlesnake (Reptilia, Serpentes, Viperidae) from Jalisco, Mexico.

Dispersal movements and plant associations of juvenile gray treefrogs, *Hyla versicolor* LeConte.

Reproduction in the mole king snake, *Lampropeltis calligaster rhombomaculata* (Serpentes, Colubridae).

Nesting habits of diamondback terrapins *(Malaclemys terrapin)* on the Atlantic coast of Florida.

Miscellaneous notes on the reproductive biology of reptiles. 4. Eight species of the family Boidae, genera *Acrantophis, Aspidites, Candoia, Liasis* and *Python.*

If not, you should consider membership in the Kansas Academy of Science. These titles have been selected from issues of the *Transactions* of the Kansas Academy of Science, and appeared from 1978 to date. The Academy has an international membership, and the quarterly *Transactions* are a high quality medium for publication of original research.

Annual membership is $12.00 ($9.00 for students). Please send your check to: Gaylen Neufeld, KAS Secretary, Division of Biology, Emporia State University, Emporia, Kansas 66801. ●

REPTILE REPRODUCTIVE BIOLOGY SYMPOSIUM

Convened by Laurie J. Vitt, this symposium should be of considerable interest to anyone interested in reptilian reproduction, behavior or physiology. Some of the more than two dozen papers to be presented are:

Intraspecific Variation in Egg and Hatchling Size of *Anolis limifrons*
R. M. Andrews and A. S. Rand
Department of Biology, Virginia Polytech Institute and Smithsonian Tropical Research Institute

The Endocrine Control of Sexual Behavior in the Male Red-sided Garter Snake *(Thamnophis sirtalis parietalis)*
B. Camazine and D. Crews
Museum of Comparative Zoology, Harvard University

Reproductive Energetics of the Painted Turtle *(Chrysemys picta)*
J. D. Congdon
Savannah River Ecology Laboratory

Lizards and Clocks: Central Refractoriness in Reptilian Reproduction
H. S. Cuellar
4330 Kinglet, Houston, Texas 77035

Reproductive Cycles in Tropical Reptiles
H. S. Fitch
Museum of Natural History, University of Kansas

Comparative Aspects of the Regulation of Vitellogenesis in Reptiles
S-m. Ho, S. Kleis, S. Taylor and I. P. Callard
Department of Biology, Boston University

Water Relations and Structure of Reptilian Eggs
G. C. Packard, M. J. Packard and T. J. Boardman
Department of Zoology and Entomology, Colorado State University

The Evolution of Reptilian Viviparity: A Review of Hypotheses and Case-Histories
R. Shine
School of Biological Sciences, University of Sydney

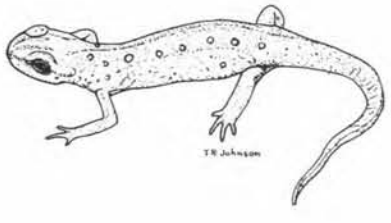
Comparative Demography of *Basiliscus basiliscus*
R. W. Van Devender
Department of Biology, Appalachian State University

Ecological and Evolutionary Determinants of Relative Clutch Mass in Lizards
L. J. Vitt and H. J. Price
Museum of Natural History and Department of Zoology, University of Georgia

Persons interested in further information on the conference should contact Dr. Vitt (Museum of Natural History, University of Georgia, Athens, GA 30602). ●

THE INTERNATIONAL HERPETOLOGICAL SOCIETY

The International Herpetological Society has been in existence since 1969. For a number of years, membership remained at around the 80 mark, but with the publication of a monthly newsletter and a quarterly journal, membership increased rapidly and now stands at 450.



The monthly newsletter is mainly concerned with Society matters and includes details of forthcoming meetings, members' letters and reports on current herpetological matters; members' advertisements are included free of charge.

The quarterly journal 'The Herptile' is professionally printed and has a bias toward the care and breeding of herps in captivity. High quality illustrations (both photographic and pen and ink) are included and colour plates appear from time to time. The journal is usually some 40 pages.

Meetings are held on the first Saturday in every month in Birmingham. Regional meetings are held annually in different parts of the U.K.

The annual subscription rates are £5.00 single, £5.50 family. Overseas members are welcomed, the rate being £5.00 (all publications forwarded by surface mail) and £6.00 (publications forwarded by air mail).

Further details can be obtained from the Secretary/Treasurer, A. J. Mobbs, 27 St. Thomas Close, Dartmouth Avenue, Walsall, West Midlands, WS3 1SZ, England. ●

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

CAUDATA

GYRINOPHILUS PORPHYRITICUS PORPHYRITICUS (Northern Spring Salamander). USA: MASSACHUSETTS: Middlesex Co: 1.2 km S of Ashby. DOR found 16 June 1969 by Eric Davis of Fitchburg State College. Verified by T. E. Graham. Fitchburg State College (FSC-061669). Extends the range one county eastward (Lazell, 1972, Reptiles & Amphibians in Massachusetts, Publ. Massachusetts Audubon Society, 35 pp.)

Submitted by **TERRY E. GRAHAM,** Department of Biology, Worcester State College, Worcester, Massachusetts 01602. ●

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: ILLINOIS: Lawrence Co: About 5.5 km W Lawrenceville, in Red Hills State Park. 18 September 1963. G. R. Thurow. Verified by H. Marx, Field Museum of Natural History. Western Illinois University Collection (WIU 106). This record was transmitted orally to P. W. Smith, and through him to R. Conant, where the record is shown on the distribution map (Conant, 1975, A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co.), but no detailed locality is given. This record details one of the sporadic localities in the southern three quarters of Illinois.

Submitted by **G. R. THUROW,** Department of Biological Sciences, Western Illinois University, Macomb, Illinois 61455. ●

ANURA

HYLA CHANEQUE. MEXICO: VERACRUZ: Sierra de Santa Marta, Arroyo Claro, approximately 26 km SE Catemaco and 14 km NE Soteapan, 1100 m above sea level. 22 September 1978. G. Pérez-Higareda. Verified by W. E. Duellman, Univ. Kansas Mus. Nat. Hist. Deposited in the herpetological collection of the Estación de Biología Tropical "Los Tuxtlas", U.N.A.M. (EBT 457). One adult specimen was found on a humid tree covered with ferns nearby a stream. This is a new state record and extends its range approximately 160 km to the northeast of the previously recorded localities (Duellman, 1970, The hylid frogs of Middle America, Mon. Mus. Nat. Hist. Univ. Kansas, Vo. 2:249-753).

Submitted by **GONZALO PEREZ-HIGAREDA,** Estación de Biología Tropical "Los Tuxtlas", Instituto de Biología, Universidad Nacional Autónoma de México, Apartado Postal 51, Catemaco, Veracruz, México. ●

TESTUDINES

PSEUDEMYS SCRIPTA ELEGANS (Red-eared Slider) USA: WEST VIRGINIA: Wirt Co: 0.8 km S Elizabeth, Little Kanawha River. July 1979, September 1980. One adult male and one adult female. James Gould. Marshall University, West Virginia Biological Survey collection (WVBS 4453-4454). Extension of range 62 km NE in the Ohio River Valley. OHIO: Lawrence Co: Floodplain of Ohio River, 1 km W Chesapeake. April 1979, two sub-adults, M. E. Seidel, (MES 752). Vesuvius Lake, April 1980, Paul Seidel, (MES 753). These records fill a gap in the range between the Scioto River, Ohio, and Kanawha River, West Virginia (Adler, 1968, J. Herpetol. 2:117-120).

Submitted by **MICHAEL E. SEIDEL** and **N. BAYARD GREEN,** Marshall University, Huntington, West Virginia 25701. ●

SAURIA

HELODERMA HORRIDUM EXASPERATUM (Rio Fuerte Beaded Lizard). MEXICO: Sonora: Movas. 5 August 1979. L. Corral and J. R. Ottley. Identified by J. R. Ottley. Brigham Young University (BYU 34504). Extends range approximately 140 km north of the Alamos-Guirocoba area (Bogert and Martin del Campo, 1956, The Gila Monster and Its Allies, Bull. Amer. Mus. Nat. Hist., vol. 109:238 pp.). Movas is in the western foothills of the Sierra Madre Occidental, a transition zone between the thorn forest and desert scrub. *H. h. exasperatum* probably occupies much of the Sonora foothill region where the thorn forest provides suitable habitat.

Submitted by **JOHN R. OTTLEY,** Department of Herpetology, 290 MLBM, Monte L. Bean Life Science Museum, Brigham Young University, Provo, Utah 84602. ●

HELODERMA SUSPECTUM CINCTUM (Banded Gila Monster). USA: CALIFORNIA: Inyo and San Bernardino counties: Kingston Range, 5.5 km ENE Horse Thief Springs, 945m 4 May 1980; 1.4 km W Porcupine Tanks, 1220m 20 May 1980; 2.6 km W Kingston Peak, 1130m 3 June 1980. R. S. Ford. Three adults sighted, no specimens taken due to protected status. Documentation made with a black and white photograph (Fig. 1). All three individuals were found in sandy washes in the vicinity of large boulders. Plant associates included *Acacia greggii, Ambrosia dumosa, Ephedra funerea, Larrea tridentata,* and *Prunus fasiculata.* Three sightings of *H. s. cinctum* have been previously reported in the Mojave Desert of California. One specimen was taken at the base of the eastern slope of the Clark Mountains (Bradley and Deacon, 1966, Copeia (2): 365-366). Another was taken from the western slope of the Providence Mountains (Brown, 1976, unpublished report prepared for the Bureau of Land Management, Riverside, California). The third was taken from the California side of Imperial Dam on the Colorado River (Funk, 1966, Herpetologica 22(4): 254-258). This report presents the fourth reported location for *H. s. cinctum* in California, and represents a 48 km range extension northwest of Clark Mountain. Bradley and Deacon (1966) also cited a specimen taken from the eastern slope of the Spring Range in southeastern Nevada. With the exception of Imperial Dam, all of these sightings are associated with cool, high desert areas. This fact supports the hypothesis that these sightings represent populations existing only as small isolated relicts of the Pleistocene epoch when the climate of the Mojave region was much cooler and the potential range of Gila Monsters much wider. *Heloderma suspectum* is recognized as a resident species in California and is fully protected by California Department of Fish and Game.

Submitted by **R. S. FORD,** Environmental Field Program, University of California, Santa Cruz, California 95064. ●

Fig. 1. *Heloderma suspectum cinctum* found in a sandy wash at the bottom of a canyon 1.4 km west of Porcupine Tanks, 1220m, Kingston Range, San Bernardino County, California, 20 May 1980.

HELODERMA SUSPECTUM SUSPECTUM (Reticulate Gila Monster). MEXICO: Sonora: 19.7 km (by Mex. Hwy 001) WNW Alamos. 9 August 1979. J. R. Ottley and K. A. Stockton. Identified by J. R. Ottley. Brigham Young University (BYU 36848). Extends the range eastward approximately 16 km into the thorn forest desert scrub transition. In July 1974 I identified and released an adult *H. horridum exasperatum* 16.8 km WNW Alamos. These observations indicate a likely range overlap between the two species in that area.

Submitted by **JOHN R. OTTLEY,** Department of Herpetology, 290 MLBM, Monte L. Bean Life Science Museum, Brigham Young University, Provo, Utah 84602. ●

PETROSAURUS THALASSINUS REPENS (Central Baja Rock Lizard). MEXICO: Baja California del Norte: Jaraguay. 9 June and 6-7 July 1978. J. R. Ottley, R. W. Murphy, and J. C. Cram. Identified by J. R. Ottley. Brigham Young University (BYU 33934-33953). Second record for subspecies in Baja California del Norte. The previous and most northerly record for this subspecies is from the Pacific drainage at a locality 17.4 km northeast of Rancho Santa Catarina (Bostic, 1971, Trans. San Diego Soc. Nat. Hist., 16:237-263). The Jaraguay specimens extend the range approximately 32 km east by southeast onto the Sierra Columbia uplift. Although *P. t. repens* and *P. mearnsi mearnsi* have not been found together, their ranges indicate a sympatric relationship in this region since the Jaraguay *P. t. repens* penetrate well into the range of *P. m. mearnsi;* the latter having been taken by us 12.8-25.6 km north (Catavina and Santa Inez, BYU 33915, 34889-34890) and 14.4 km south (El Pedregoso, BYU 33916) of Jaraguay.

Submitted by **JOHN R. OTTLEY,** Department of Herpetology, Monte L. Bean Life Science Museum, 290 MLBM, Brigham Young University, Provo, Utah 84602, and **ROBERT W. MURPHY,** Department of Biology, University of California, 405 Hilgard Avenue, Los Angeles, California 90024. ●

SERPENTES

CARPHOPHIS AMOENUS AMOENUS (Eastern Worm Snake). USA: NEW YORK: Albany Co: corner of Everett Road and Watervliet Avenue extension, West Albany. 26 June 1975. D. Bauer. 322 mm total length. New York State Museum (NYSM 32864). NEW YORK: Albany Co: west Albany 27 May 1976 male, 240 mm total length. 3 June 1976 female, 285 mm total length, taken and released, John Rossi. NEW YORK: Albany Co: Karner's Corners, Amoena Brook specimen taken 20 May 1902, (NYSM 102), D. A. Trask. The recent records follow a period of 73 years without any report of the species in the Albany area. The nearest known area of occurrence in New York is in Orange County, Bear Mountain State Park, Lake Tiorati, (144 km to the south). The Albany Pine Plains, where the worm snake occurs, is under the threat of development and the northernmost known colony of this species may soon disappear. The Pine Plains lie between the cities of Albany and Schenectady; fourteen species of amphibia and thirteen reptile species have been recorded in the area during recent surveys by Rossi.

Submitted by **E. M. REILLY, JR.,** N.Y.S. Museum and Science Service, Cultural Education Center, Room 3140, Albany, New York 12230 and **JOHN ROSSI,** Biology Department, University of South Florida, Tampa, Florida 33612. ●

CROTALUS VIRIDIS HELLERI (Southern Pacific Rattlesnake). MEXICO: Baja California del Sur: *ca.* 7 km E Guerrero Negro. 8 April 1974 S. G. Bennett. Verified by R. B. Loomis. LACM 132250. This snake was maintained in the live herpetological collection at California State University, Long Beach for nearly seven years. This is the second record of this species (and subspecies) from Baja California del Sur. It was found approximately 50 km W and slightly N of the other specimen from 14 km S El Arco (Smith, H. M., R. L. Holland and R. L. Brown. 1971. The prairie rattlesnake in Baja California del Sur. J. Herpetol. 5(3-4):200.). These two specimens represent the southernmost limit for this subspecies.

Submitted by **LAWRENCE L. C. JONES,** Department of Biology, California State University, Long Beach, Long Beach, California 90840. ●

CROTALUS VIRIDIS HELLERI (Southern Pacific Rattlesnake). MEXICO: Baja California del Sur: 25.6 km (by paved road) SSW El Arco, BCN. 17 July 1979. J. R. Ottley and L. E. Hunt. Identified by J. R. Ottley. Venom Research Lab, V.A. Hospital, Salt Lake City and Brigham Young University (BYU untagged). Represents the second known record of the subspecies for the state and extends the known range 9.6 km to the south (Smith et al., 1971, J. Herp., 5:200). The specimen is an adult female with a total length of 775 mm and fits the parameters set for the subspecies (Klauber, 1972, Rattlesnakes, Univ. California Press, Berkeley and Los Angeles) with a slight tail-pattern alteration in that the juvenile yellow-gold color is retained.

Submitted by **JOHN R. OTTLEY,** Department of Herpetology, Monte L. Bean Life Science Museum, 290 MLBM, Brigham Young University, Provo, Utah 84602, and **LAWRENCE E. HUNT,** Division of Herpetology, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

DROMOPHIS LINEATUS. KENYA: Nyanza Province: Kisumu Dist: Chemelil. 11 October 1976. Leo G. Hoevers. Verified by Robert C. Drewes, California Academy of Sciences (CAS 147997). First record of the genus from Kenya; adult female; stomach contents a large *Bufo.*

Submitted by **LEO G. HOEVERS,** P.O. Box 177, Muhoroni, Kenya; Field Associate, California Academy of Sciences, San Francisco. ●

DUBERRIA LUTRIX ATRIVENTRIS. KENYA: Western Province: Kakamega Dist: Mumias. 17 January 1976. Leo G. Hoevers. Verified by Robert C. Drewes, California Academy of Sciences (CAS 141532). First record of the subspecies from Kenya.

Submitted by **LEO G. HOEVERS,** P.O. Box 177, Muhoroni, Kenya; Field Associate, California Academy of Sciences, San Francisco. ●

MEIZODON CORONATUS. KENYA: Nyanza Province: Kisumu Dist: Chemelil. 7 October 1978. Leo G. Hoevers. Verified by Robert C. Drewes, California Academy of Sciences (CAS 150931). Known previously from Tana River delta, new record extends range ca. 600 km northwest.

Submitted by **LEO G. HOEVERS,** P.O. Box 177, Muhoroni, Kenya; Field Associate, California Academy of Sciences, San Francisco. ●

PITUOPHIS MELANOLEUCUS MUGITUS (Florida Pine Snake). USA: Florida: Dade Co: Old Cutler Road, between 177 and 176 streets. 16 February 1980. Dorie Karl and Gary Patterson. Verified by Peter Meylan (Florida State Museum). Florida State Museum (UF 45970). This is the second record for this species in Dade County. The previous record (University of Miami UMRC 55-394) reported by Duellman and Schwartz (1958. Amphibians and reptiles of southern Florida. Bull. Florida St. Mus. Biol. Sci. 3(5):181-324.) lists southwestern part of Miami as the locality. Additional evidence suggests that their specimen may have been an escaped pet (Albert Schwartz, pers. comm.). No evidence was found to suggest that this present specimen was an escaped pet. This record extends the southern range given by Carr and Goin (1955. Reptiles, Amphibians, and Freshwater Fishes of Florida. University of Florida Presses; Gainesville.) a minimum of 75 km.

Submitted by **TODD M. STEINER,** Archbold Biological Station, Route 2, Box 180, Lake Placid, Florida 33852. ●

POLEMON CHRISTYI. KENYA: Western Province: Kakamega Dist: Kakamega Forest. 22 December 1977. Leo G. Hoevers. Verified by Robert C. Drewes, California Academy of Sciences (CAS 147905). Second known specimen from Kenya, submitted because of record size (850 mm, female).

Submitted by **LEO G. HOEVERS,** P.O. Box 177, Muhoroni, Kenya; Field Associate, California Academy of Sciences, San Francisco. ●

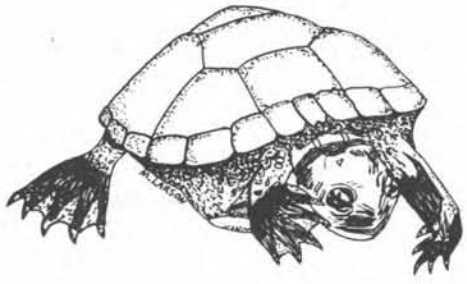
RHINOCHEILUS LECONTEI LECONTEI (Western Longnose Snake). USA: California: Monterey Co: Palo Colorado Canyon, 22.5 km SSE Carmel Highlands. 12 July 1967. DOR. Steve Moore. Verified by John Davis. Pacific Grove (California) Museum of Natural History (PGMNH R/1). Hastings Natural History Reservation, 4 km E Jamesburg. 9 June 1973. DOR. Ruth Griffin. Verified by John Davis. MVZ 175787. First records for Monterey County and extend distribution 60 km WSW and 42 km SW, respectively, of previously recorded nearest locality (near Cook P.O., Bear Valley, San Benito County, California).

Submitted by **JOHN DAVIS,** Hastings Reservation, Star Route, Box 80, Carmel Valley, California 93924, and **PHILIP A. MEDICA,** University of California, Laboratory of Biomedical and Environmental Sciences, P.O. Box 495, Mercury, Nevada 89023. ●

SALVADORA GRAHAMIAE LINEATA (Texas Patchnose Snake). USA: TEXAS: Llano Co: 13.4 km S of Llano off TEX 16. 29 March 1981. C. T. McAllister. Verified by E. G. Zimmerman. Arkansas State University Herpetol. Mus. (ASUHM 3941). First record for the county and fills the Edwards Plateau distributional hiatus between the adjacent Mason, Gillespie, Blanco, Burnet and San Saba Counties (Raun and Gehlbach, 1972. Amphibians and Reptiles in Texas, Dallas Mus. Nat. Hist. Bull. No. 2).

Submitted by **CHRIS T. McALLISTER, MICHAEL C. WOOTEN** and **TIMOTHY L. KING,** Department of Biological Sciences, North Texas State University, Denton, Texas 76203. ●

VIRGINIA VALERIAE (Smooth Earth Snake). USA: ILLINOIS: McDonough Co: About 3.5 km W Macomb (Sec. 27, T6N, R3W). 25 June 1978. R. Henry. Verified by H. Marx, Field Museum of Natural History. Western Illinois University Collection (WIU 641). Duplicate specimens seen or collected between 1968-1980 by G. Thurow from two nearby localities also N of the east fork of the LaMoine River; from within Macomb city limits; and from S McDonough County near Grindstone Creek, and near Camp Creek. One specimen also identified from the valley just below the dam at Siloam Springs State Park, Adams County. First records for McDonough and Adams counties, and fills in a west central Illinois northern gap (Conant, 1975, A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co.).



Submited by **G. R. THUROW,** Department of Biological Sciences, Western Illinois University, Macomb, Illinois 61455. ●

OBSERVATIONS ON *CARETTA C. CARETTA:* A RECORD INTERNESTING MIGRATION IN THE ATLANTIC

On 9 July 1979, at Cape Lookout National Seashore, Carteret County, North Carolina, a nesting female Atlantic loggerhead, *Caretta c. caretta,* was observed approximately 4.8 km north of Cape Point. Over-curvature carapace measurements were 97.5 cm in length and 92 cm in width. Maximum head width was 21 cm. Jumbo Roto Tags, NC0024 and NC 0025, were attached to the front flippers.

On 28 July 1979, at Canaveral National Seashore, Brevard County, Florida, the same female was observed laying a clutch of eggs on Playalinda Beach, approximately 1.5 km north of Florida Route 402. During the 19-day interval that occurred between nestings on the two rookery beaches, the turtle had moved a minimum (point to point) distance of 725 km. These observations constitute the longest single season internesting migration record known for *Caretta c. caretta* in the Atlantic Ocean.

A PERIPHERAL MEXICAN RECORD FOR *CROTAPHYTUS RETICULATUS* FOUND ERRONEOUS

The Múzquiz, Coahuila, record for *Crotaphytus reticulatus* has been a source of annoyance to interested herpetologists for some time. Based on a specimen collected 10 May 1938 by Ernest G. Marsh, FMNH 28612 is important because it represents a record well within the known range of *C. collaris* in north-central Coahuila (Montanucci, 1971, 1974). This implied sympatry has been the focus of at least two unsuccessful attempts to find additional *C. reticulatus* in the Múzquiz area (Montanucci, 1974:96). On a recent visit to the Field Museum, I probed the history of this record as I have long doubted its veracity. Reference to the permanent Museum catalog showed nothing unusual, so I decided to compare Marsh's original field numbers against the Museum's entry. On page 87 opposite field number 90, Marsh entered the following: "large lizard collected 10th [May] 2 mi. N. of Nava [Coahuila]." Marsh's field number 90 also appears on the line bearing the number FMNH 28612 in the Field Museum's catalog. I found no other *Crotaphytus* collected on 10 May nor any other collared lizard listed as coming from "Múzquiz" in Marsh's catalog.

Allan Resetar, a member of the Museum staff, tells me that he has located several entries in the permanent catalog that disagree with Marsh's original field numbers.

Interestingly, Schmidt and Owens (1944) listed the Nava locality in their work on northern Coahuila, but they indicated no catalog number. The citation thus became a literature record, but when inquiries were made about the specimen's whereabouts, it could not be located on the Museum's shelves.

I thank Allan Resetar and Hyman Marx for numerous courtesies extended. Mary Stephenson graciously typed the manuscript.

ADDITIONS TO THE SNAKE FAUNA OF EL SALVADOR

Although the herpetofauna of El Salvador is relatively well known, recent work has demonstrated the presence of four additions to the known snake fauna of this country. These additions are discussed below.

Crisantophis nevermanni (Dunn)

Crisantophis nevermanni is known to range from the vicinity of San José, Costa Rica (Río Poás de Aserrí), through central and western Nicaragua to southern Honduras (Villa, 1969, 1971; Wilson, McCranie, and Porras, 1979). This report records its occurence in El Salvador.

The Salvadoran specimen of *C. nevermanni* (MHNES 30-216) was collected on 7 May 1977 at an elevation of 250 m in Cantón San Antonio Chávez, 10 km N San Miguel, Departamento de San Miguel. This place is within the Subtropical Moist Forest (Hot) formation of Holdridge (1975).

The specimen is a male with the following characteristics: ventrals, 166; anal plate divided; subcaudals, 84; dorsal scale smooth; dorsal scale reduction formula *19* 3+4(90) *17* (166); supralabials, 8-8, with 4th and 5th entering orbit; infralabials, 9-10; loreal, 1-1; preoculars, 2-2; postoculars, 2-2; temporals, 2+2 on the left and 2+3 on the right; total length, 632 mm; tail length, 175 mm. The color in preservative (alcohol) is: dorsal ground color dark brown, with four narrow white stripes running length of body; the lateral pair of these stripes is on the 1st and 2nd rows; the dorsolateral pair is on the 6th and 7th rows. Each dorsolateral stripe originates immediately posterior to the rostral and passes posteriorly to the nape along the canthus rostralis and the lateral margin of the supraocular scale. Dorsum and sides of head dark brown; supra- and infralabials white with black sutures; supralabials with black dorsal margins. Ventral ground color white, with black flecks on the lateral margins of the ventral scales. The hemipenis may be described as follows: subcylindrical; bilobed; when everted reaches the 12th subcaudal; basal two-thirds naked; covered distally by minute spines, these becoming scarcer towards the middle; *sulcus spermaticus* bifurcates at the 9th subcaudal.

The scutellation and color pattern of the Salvadoran specimen agree well with Dunn's (1937) original description and with those given by Wellman (1963) and Villa (1969, 1971). The ventral count (166), however, even though approximate, is well below the lower end of the range of *C. nevermanni* (173-183). This number of ventrals falls within the known range of *Conophis lineatus dunni* (159-178) as given by Wellman (1963). Examination of the hemipenes of both species, however, demonstrates that the specimen from El Salvador is *Crisantophis nevermanni*.

Ninia atrata (Hallowell)

Until recently *Ninia atrata* was known no further north than Costa Rica (Burger and Werler, 1954; Dunn, 1935), but Meyer and Wilson (1971) have recently recorded this species in southwestern Honduras. In May 1979, I collected 4 specimens (HH 604-07) in Cantón Palo Blanco, 10 km NE Perquín, Departamento de Morazán. The Salvadoran specimens came from an area that falls within the Subtropical Lower Montane Moist Forest formation of Holdridge (1975), at an elevation of 1900 m. They were collected from under logs, clumps of fallen orchids in the forest, and piles of cornstalks in a clearing.

The specimens from El Salvador are all males with the following characteristics: ventrals, 142-146; anal plate single; subcaudals, 50-60 (3 specimens); dorsal scales keeled and striated; dorsal scales in 19 rows throughout; supralabials, 7-7, with 3rd and 4th entering orbit; infralabials, 7-7; loreal enters orbit; preoculars absent: postoculars, 2-2; temporals, 1+2; body length, 205-325 mm; tail length, 56-78 mm (3 specimens). The color in life was: dorsum dark gray; no pale nuchal collar; supralabials cream; venter cream, immaculate or with some dark gray fleckings; ventrals with dark gray outer margins; underside of tail dark gray, becoming most pronounced posteriorly.

Scale counts of the four Salvadoran specimens fall within the ranges given for *N. atrata* by Burger and Werler (1954). Regarding coloration, typical *N. atrata* have a pale nuchal collar. The Honduran specimens reported by Meyer and Wilson (1971), however, were collarless. Similarly, Roze (1966) stated that this collar may be completely absent in some Venezuelan specimens. This collarless pattern is also shared by the Salvadoran specimens I have examined, which, because of this fact, I regard as representatives of *Ninia atrata*. As more material becomes available, it will be possible to better determine the extent of variation of this species in northern Central America.

Sibon nebulata (Linnaeus)

Peters (1960) recorded the range of *Sibon nebulata* as extending from Michoacán and Campeche in México, including all of the Yucatán Peninsula, south to Ecuador and Brasil and the islands of Trinidad and Tobago. This species had been expected to occur in El Salvador but previously no specimens have been collected there.

A single specimen of *S. nebulata* (CG 26) is now available from El Salvador. It was collected in November 1973 in the region of Laguna San Diego, Hacienda San Diego, 6 km S Metapán, Departamento de Santa Ana, altitude 450 m. The snake was captured at night in a tangle of vines growing on volcanic lava (Tropical Dry Forest formation of Holdridge, 1975).

The Salvadoran specimen is a female and has the following characteristics: ventrals, 185; anal plate single; subcaudals, 90; dorsal scales smooth; dorsal scale rows 15 throughout; supralabials, 7-7, with 4th and 5th entering orbit and 6th enlarged; infralabials, 8-7, first pair in contact behind mental; loreal enters eye; no preoculars; postoculars, 2-2; temporals, 1+2; mental groove present; 3 pairs of chin shields; total length, 707 mm; tail length, 184 mm. The color in preservative (formalin) is: dorsal ground color yellowish white; body with 40 irregular chocolate brown blotches, joined ventrally, with cream edges; interspaces pale brown variegated with blotch color, from 1-4 scales wide; supralabials and infralabials cream, with chocolate brown sutures; dorsum of head pale brown stippled with chocolate brown; temporals uniform chocolate brown. Ventral ground color cream. Tail with 15 rings colored as body.

In scutellation and color, the Salvadoran specimen agrees well with the descriptions given by Peters (1960) and Roze (1966) for *S. n. nebulata*, the subspecies expected to occur in this area.

Thamnophis fulvus (Bocourt)

Meyer and Wilson (1971) have recently recorded this snake (as *Thamnophis cyrtopsis*), a species previously unknown south of Guatemala (Stuart, 1963), in southwestern Honduras. Webb (in press) has demonstrated the specific distinctness of *Thamnophis fulvus* from *T. cyrtopsis*. On 5 April 1979 I collected 3 specimens at Cantón El Zancudo, 12 km NE Perquín, Departamento de Morazán. This locality is within cloud forest (Subtropical Lower Montane Moist Forest formation of Holdridge, 1975), at an elevation of 1800 m. These snakes were captured at night in ponds of a creek in a grassy meadow.

The Salvadoran specimens are one male (HH 609) and two females (HH 610-11) and have the following characteristics, in that order: ventrals, 147, 142, 143; anal plate single; subcaudals, 71, 64, 64; dorsal scales keeled, first row weakly keeled; dorsal scale row formula, 19-17; supralabials, 8-8, with 4th and 5th entering orbit; infralabials, 9-10, 10-10, 10-10; loreals, 1-1; preoculars, 1-1; postoculars, 3-3; temporals, 1+2 or 1+3; body length, 350, 383, 408 mm; tail length, 118, 118, 119 mm. The color in life was: dorsal ground color olive to olive brown, with an incomplete vertebral and 2 lateral whitish yellow stripes, these becoming pale brown posteriorly; vertebral stripe separates 2 large black blotches on the nape; dorsum with 2 alternating rows of black spots above lateral stripe; black spots fade posteriorly; lateral stripe confined to 2nd and 3rd scale rows; a series of black spots on the 1st scale row present or absent. Dorsum of head olive brown; supralabials grayish white, with black sutures. Ventral ground color whitish to greenish gray; infralabials and chin creamish white; outer margins of ventrals olive or olive brown. Tongue all black. These specimens are obviously referable to *Thamnophis fulvus*, as defined by Webb (in press).

For allowing me to examine specimens used in the preparation of this paper, I am indebted to Sr. Carlos Guillén, (CG private collection); and Srita. Maria E. Sánchez, Museo de Historia Natural de El Salvador (MHNES). My thanks are also extended to Sres. Miguel A. Ramírez, José García, Roque García for their field assistance, and Gilberto Argueta for his hospitality at Cantón El Zancudo. I am especially grateful to Drs. Larry D. Wilson, Thomas H. Fritts, Robert G. Webb, and Mr. Van Wallach for providing me with

helpful information. In addition, I sincerely thank Drs. Larry D. Wilson and W. Ronald Heyer for criticizing the manuscript. Sra. Estela de Gómez typed the manuscript. The initials HH refer to my private collection in El Salvador.

PROBABLE NATIVE POPULATION OF BULLFROG, *RANA CATESBEIANA,* IN SOUTH TEXAS

The bullfrog, *Rana catesbeiana* Shaw, is a large ranid native to most of the United States east of the Rocky Mountains, but its "natural western limits are now hopelessly confused" (Conant, 1975, A field guide to reptiles and amphibians of eastern and central North America, Houghton Mifflin Co., Boston). *R. catesbeiana* occurs over most of Texas except for the more arid western sections and was "probably absent from the Edwards Plateau, southern Texas south of Nueces County, and the Trans-Pecos region" (Raun and Gehlbach, 1972, Bull. Dallas Mus. Nat. Hist. 2(1):1-61). The only contemporary report of the bullfrog from Webb County (Karges, 1979, Herp. Rev. 10:119-121) are stock pond specimens which may represent introductions.

On 22 February 1828 a Mexican boundary expedition camped at La Parida, Webb County, at which point the expedition "heard for the first time the frog whose astounding call resembles the bellowing of a bull. This frog is rarely seen and is as large as the head of a man. The croaking, by its monotony and marked rhythm does not fail, in the silence of night, to arouse sadness" (Sanchez, trans. by Castaneda, Southwestern Hist. Quart. 29: 250-288). This species was different from the "water frogs" (probably *Rana berlandieri*) which were sighted elsewhere.

This bullfrog locality report (unfortunately not substantiated by a specimen) extends the known native range of *R. catesbeiana* in south Texas approximately 180 kilometers west of Nueces County. The Webb County record was along Beccero Creek, a tributary of San Casimiro which flows into the Nueces River. The previously accepted native range of *R. catesbeiana* followed approximately the boundaries of the Austroriparian and Texan Biotic Provinces (Blair, 1950, Tex. T. Sci. 2:93-117). This new record extends the native range into the Tamaulipan Biotic Province which is characterized by scrub brush, i.e. chapparal, vegetation. While the Nueces River allows a mesic strip of dilute Austroriparian biota to intrude upon this area, the Beccero Creek locality was 24 to 34 km southwest of the Nueces River channel.

The biogeographical origin of this population can never be determined with certainty. *R. catesbeiana* may have migrated up the Nueces drainage during a very recent mesic period, e.g. the Little Ice Age (see Price and Gunter, 1942, Trans. Tex. Acad. Sci. 26:138-156). Subsequent drought periods would have restricted suitable bullfrog habitat to small areas of permanent water on generally intermittent drainages. Existence of this population could date from Late Wisconsin-Early Holocene times when *R. catesbeiana* existed in areas of the Balconian Biotic Province where it did not apparently occur naturally within historical times (Holman, 1966, Tex. T. Sci. 28:372-377).

TEXAS AMPHIBIANS AND REPTILES: SOME NEW DISTRIBUTIONAL RECORDS, PART III

This is the third serial report of new distributional records of Texas amphibians and reptiles (see Karges 1978, 1979), substantiated with specimens in the Texas A & I University Collections (TAIC). These records are additions since Raun and Gehlbach (1972), and are from two south Texas counties, Jim Hogg and Zapata. Parenthetical numbers refer to the numbers of individuals, in a series, with a single TAIC catalogue number. Nomenclature follows Collins, *et al.* (1978), and I verified the identifications. I thank Dr. A. H. Chaney for access to the collection and R. R. Schmidt for allowing me to report on specimens that he collected.

CAUDATA

Ambystoma tigrinum mavortium (Barred Tiger Salamander); JIM HOGG Co. 2.9 km WSW Hebbronville. 6 February 1970. J. A. Rickner, *et al.* TAIC-1391(46). 16.1 km SW Hebbronville. 12 April 1969. G. Ellison, TAIC-1960.

SALIENTIA

Bufo marinus (Giant Toad): JIM HOGG Co. 30.1 km S Hebbronville on TX 16. 4 June 1978. R. R. Schmidt. TAIC-4367. 10.7 km S Randado on FM 649. 4 June 1978. J. P. Karges. TAIC-4490. Both specimens were taken on brushland roads at night and confirm range-margin extension in this county. Axtell and Wasserman (1953) reported that Blair (1947) released several *Bufo marinus* near Hebbronville although Blair only alludes to release in his note. It seems unlikely that these two specimens are from that stock because of the distance of capture localities from Hebbronville and because I found seven other DOR *Bufo marinus* (unpubl. field notes) between Randado and the Starr Co. line, a 41.6 km stretch of FM 649, on the same night. It appears that *Bufo marinus* has an extensive distribution in Jim Hogg Co.

SERPENTES

Hypsiglena torquata jani (Texas Night Snake): JIM HOGG Co. 12.9 km S Hebbronville on TX 16. 4 June 1978. R. R. Schmidt. TAIC-4384.

Masticophis flagellum testaceus (Western Coachwhip): JIM HOGG Co. 2.2 km SE Hebbronville on FM 1017. 6 May 1978. J. P. Karges & S. White. TAIC-4310.

Masticophis taeniatus schotti (Schott's Whipsnake): JIM HOGG Co. 3.2 km S Randado on FM 649. 4 June 1978. J. P. Karges. TAIC-4398.

Rhinocheilus lecontei tessellatus (Texas Longnose Snake): JIM HOGG Co. 2.1 km W Hebbronville on TX 359. 29 April 1978. J. P. Karges & R. R. Schmidt. TAIC-4268. ZAPATA Co. Bustamante. 4 June 1978. R. R. Schmidt. TAIC-4365. 27.4 km NW Zapata on TX 16. 5 June 1978. R. R. Schmidt & J. P. Karges. TAIC-4389.

Salvadora grahamiae lineata (Texas Patchnose Snake): JIM HOGG Co. 1.6 km NE Hebbronville. 31 May 1968. J. Davis. TAIC-1524.

NEW *HR* SECTION

HR's feature article file is burgeoning to the point of ridiculousness, and the current lag time to publication is about 18 months. A number of manuscripts on "hold" are ones which could be condensed into rather brief notes, following the same general format as ***GEOGRAPHIC DISTRIBUTION.*** Hence, beginning with this issue, ***HR*** will start a ***LIFE HISTORY NOTES*** section analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (*e.g.*, Reproduction, Longevity, Coloration, Morphology, *etc.*). Figures are permissible to illustrate any data, but should ***REPLACE*** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses — use Collins, *et al.* 1978. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles wherever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Additionally, I shall review our stock of articles on hand and begin to reformat manuscripts best suited to this section. I do not expect this to cause trauma to authors, but should you ***NOT*** want your paper expedited into print, please let me know. ***GRP***

LIFE HISTORY NOTES

CAUDATA

CRYPTOBRANCHUS ALLEGANIENSIS (Hellbender) **LONGEVITY.** Bowler (1977. Longevity of reptiles and amphibians in North American collections. SSAR Herp. Circ., 6:1-32) reported 6 years the maximum longevity for a wild-caught, captive hellbender in a North American collection. Nickerson and Mays (1973. The hellbenders: North American "Giant salamanders." Publ. Biol. Geol. Milwaukee Pub. Mus., 1:1-106) published reports of ages of 30 and 55 years based on specimens maintained in collections outside North America.

On 24 June 1972, Max A. Nickerson collected an adult hellbender in the Niangua River, 0.8 km downstream from Bennett Springs, Dallas County, Missouri. It was donated to the Museum of Natural History, University of Kansas, where it has been maintained alive as of this date, a longevity of over ten years. It has been kept at room temperature in a thirty gallon aquarium with gravel substrate, and fed newborn mice on a weekly basis. It appears to be thriving and will be placed at the Oklahoma City Zoo in the near future.

A number of persons have cared for the hellbender since its arrival at the Museum, and they deserve credit for the success in maintaining it. They are: Janice J. Perry, Ray E. Ashton, Andrea Stammler, Mary E. Dawson, Kelly J. Irwin, Eric M. Rundquist and Hank Guarisco.

Submitted by **JOSEPH T. COLLINS,** Museum of Natural History, University of Kansas, Lawrence, Kansas 66045 *and* Research Associate, Dallas Zoo, 621 East Clarendon Drive, Dallas, Texas 75203. ●

AMBYSTOMA TALPOIDEUM (Mole Salamander) **MORPHOLOGY.** A five-legged mole salamander *(Ambystoma talpoideum)* was collected on 5 March, 1981 from a pitfall trap and drift fence at Flamingo Bay, Aiken County, South Carolina (Fig. 1). The specimen was a gravid female with a snout-vent length of 54.5 mm. Both legs are functional, but only one leg at a time is used for locomotion, alternating between the two limbs. An X-ray indicated the extra limb has a normal skeletal structure.

This anomaly apparently occurs infrequently in natural populations. While monitoring five breeding populations of *A. talpoideum* and recording greater than 17,935 original captures (8,590 juveniles, 9,345 adults) since 1978, a five-legged individual has occurred only once, a resultant frequency of 0.000056. Other abnormalities recorded include at least two individuals with forked tails and dozens with forked and fused toes, the latter often being induced from toe-clipping.

TURTLES IN KANSAS

by

Janalee P. Caldwell and Joseph T. Collins

This book presents complete and concise information on the fourteen kinds of turtles currently known to occur in Kansas. Each of these turtles is treated in an account which contains one or more color photographs, common and scientific name, and descriptions of its size and identifying characteristics, habitat, breeding habits, food preferences, predators, defense mechanisms, general range, species with which it might be confused, how to observe it in the wild, and a **detailed** map of its distribution in Kansas.

In addition, this book contains a non-technical key for identifying living turtles, and an illustrated technical key to preserved specimens of turtles for use by biology classes. 80 pages, 16 color photographs, $5.25 each, postage paid. (Kansas residents add 3.5% sales. Outside U.S. add 5% handling.)

SERPENTES

CROTALUS ATROX (Western Diamondback Rattlesnake). **COLORATION.** An adult male, approximately 85 cm. in total length, collected spring of 1981 by Harry and Bill Sakewitz, near the town of Manor, in northeast Travis County, Texas.

The snake is completely patternless except for a dull yellow stripe in front of each eye, which is similar to that found in typical morphs. The dorsum is uniformly gold-brown in color and the tail, instead of having alternating black and white bands, is solid black suffused with the gold-brown dorsal color. Other aberrant color patterns have been found in *Crotalus atrox* (Klauber, L. M. 1972. Rattlesnakes. Their habits, life histories, and influence on mankind. University of California Press, Berkeley and Los Angeles. 2 Vols.; Nickerson, M. A. and C. E. Mays. 1968. More aberrations in the color patterns of rattlesnakes (genus Crotalus). Wasmann Journal of Biology. 26(1):125-131). However, I have found no other examples of this variation in the literature.

This snake is presently being exhibited alive in the reptile collection of the San Antonio Zoo and will be used for breeding experiments. Upon its death, it will be added to the zoo's collection of preserved specimens.

Submitted by **ERIK HOLMBACK,** Reptile Dept./San Antonio Zoo, 3903 N. St. Mary's St., San Antonio, TX 78212. ●

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted. Citations should be sent to

Herpetology of Brazil

COMPRISING THREE BOOKS BY J. B. VON SPIX AND J. G. WAGLER
TOGETHER WITH A NEW INTRODUCTION BY P. E. VANZOLINI (SAO PAULO)

about 400 pages (including 98 plates); 8 1/2 by 11 inches; index

IN 1817 Johann Baptist von Spix and his colleague Karl-Friedrich-Philipp von Martius, a botanist, set out from Bavaria on a three-year exploration of Brazil. Besides collections of plants and other animals, those of amphibians and reptiles provided the most comprehensive and important early survey of the herpetology of Brazil and, indeed, of all of South America. Some 155 species were described, most of them newly discovered, as well as first descriptions of such familiar genera as *Bothrops, Micrurus, Kinosternon* and *Caiman* among others. All species were beautifully illustrated in detailed, full-page plates, one of which is reproduced in color.

This reprint edition includes the original volumes (first published in Munich, 1824-25) plus an extensive new introduction by Professor Vanzolini which gives an itinerary for the Spix-Martius expedition (with map) through the Atlantic forests, the caatingas of northeastern Brazil and up the Amazon River to the Peruvian border. In addition, there is an historical discussion of the expedition; tables of species names with modern equivalents to bring the nomenclature up to date; a detailed review of the type localities; and an announcement of the rediscovery of Spix's and Wagler's type specimens in Munich and Leiden.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted **must** be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white, 8 X 10, glossy prints, and should be accompanied by a descriptive caption and exposure data. The name and address of the contributor should be taped or penciled on the back of each print. Please DO NOT send photographs before corresponding with the editors about them. Return of the unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from Barbara Paschke, **HR** Associate Editor, 731 Tennessee Street, Lawrence, Kansas 66044 USA.

SSAR ANNUAL MEETING NEWS

Fig. 1. The Administration Building is located in the center of the 60 ha Main Campus. It houses administrative offices and the University's computer facilities.

HERPETOLOGY AT MEMPHIS STATE UNIVERSITY

The 1981 joint annual meetings of The Society for the Study of Amphibians and Reptiles and The Herpetologists' League will be hosted by Memphis State University with Dr. James S. Jacob serving as local chairman. The host institution was founded in 1912 as West Tennessee State Normal School on the site of an old plantation. In 1925 the name was changed to West Tennessee State Teachers College and the curriculum was expanded to a four-year program. The name was shortened five years later to State Teachers College, and in 1941 the institution became Memphis State College. The undergraduate program was reorganized into three schools in 1951 and a graduate school was added. In 1957, by action of the Tennessee Legislature, the institution was designated Memphis State University. The University, with an enrollment of approximately 21,000, is comprised of eight schools and colleges: Graduate School, Cecil C. Humphries School of Law, College of Arts and Sciences, Fogelman College of Business and Economics, College of Communication and Fine Arts, College of Education, Herff College of Engineering, and University College. Seventeen undergraduate degrees in 60 different programs are offered through the seven undergraduate colleges. The Graduate School offers nine Masters degrees in 57 programs and three Doctoral degrees in six departments. The Division of Public Service and Continuing Education offers a wide variety of credit and non-credit courses and programs both on and off campus.

The Department of Biology, consisting of 32 faculty, occupies two buildings on Main Campus, Ellington Biological Sciences and Life Sciences. The Ecological Research Center, which houses the Museum of Zoology and most of the vertebrate zoology research laboratories, is located on South Campus. M.S. and Ph.D. degrees in biology are offered by the department with concentrations in Botany, Cell and Molecular Biology, Invertebrate Zoology, Microbiology, and Vertebrate Zoology. Located in the Life Sciences Building, The Center for Electron Microscopy houses both scanning and transmission instruments. Support facilities such as this and Computer Services are available for graduate student and faculty research at no cost to the investigator. Meeman Biological Field Station is located ca. 40 km north of Memphis adjacent to Meeman-Shelby Forest State Park, Shelby Wildlife Management Area, and the Mississippi River.

Dr. Jacob joined the faculty in 1977. He is currently involved in a scanning electron microscopy study of the lungs of the copperhead, *Agkistrodon contortrix*, and cottonmouth, *A. piscivorus*. Three students have recently completed undergraduate herpetological problems. Anita M. Steed, now at The University of Oklahoma pursuing an M.S. with Dr. Charles C. Carpenter, worked on comparative morphology and histology of the lungs of *Agkistrodon contortrix* and *A. piscivorus*. The effect of temperature on the heart rate-ventilatory response in *Agkistrodon contortrix* was investigated by Steven L. Carroll. Michael A. Rinehart looked at female reproductive cycle of *Agkistrodon piscivorus* in western Alabama. Four graduate students are pursuing Masters degrees under the supervision of Dr. Jacob. J. Stephen Sanders' thesis topic is thermal ecology of *Agkistrodon contortrix*. He is also working on microdermatoglyphics of selected colubrid snakes and thermoregulation of six-lined racerunner, *Cnemidophorus sexlineatus*, in western Ten-

Fig. 2. John Willard Brister Library houses more than 700,000 bound volumes and *ca.* 1,000,000 pieces of micromaterial.

Fig. 3. Malls have been constructed at MSU in an effort to establish a pedestrian campus. The original Brister Library Building (left rear) is one of the oldest structures on campus and was recently added to the National Register of Historic Places.

nessee. Leslie F. Johnson has just completed work on a project looking at the male reproductive cycle of *Agkistrodon piscivorus* in western Alabama. Her thesis research in an investigation of the relationship between pituitary activity and male reproductive cycle of *Cnemidophorus sexlineatus* in Tennessee. Comparative parasite loadings in *Agkistrodon piscivorus* and three species of *Nerodia* from western Alabama is James L. Detterline's thesis project. James J. Greenhaw has just begun work on the reproductive cycle of male rough green snakes, *Opheodrys aestivus*, in central Arkansas. Samuel L. Reynolds recently finished his Masters at Marshall University with Dr. Michael E. Seidel and has just started work on his Ph.D. with Dr. Jacob. His thesis was titled "Electrophoretic and morphological analysis of the musk turtle, *Sternotherus odoratus*." Dr. Lewis B. Coons, Director of The Center for Electron Microscopy, has recently begun a project with Dr. Jacob looking at the ultrastructure of lung parenchyma in *Agkistrodon contortrix* and *A. piscivorus*.

Since Jacob's arrival at MSU, the Collection of Amphibians and Reptiles in the Memphis State University Museum of Zoology has expanded rapidly. Specimen collection data will soon be placed on computer files, using the SELGEM program for data retrieval. The emphasis of the collection is in the Mid-South area, much of which is poorly known herpetologically.

Reproductive Biology of Reptiles will be the topic for the featured symposium. It is scheduled for Monday through Wednesday, 10-12 August. Dr. Ernest Williams will present the first Distinguished Herpetologist Lecture, sponsored by The Herpetologists' League, on Monday, 10 August. Student paper awards presented by the societies at the Memphis meetings will include additional prizes donated by David M. Dennis and Ben Greishaw. David Dennis is providing a set of his magnificent prints to SSAR for the Kennedy Award. Ben Greishaw is giving The Herpetologists' League one of his exquisite wood carvings of a hatching turtle for the HL student prize. Several commercial supply firms and publishers are helping to sponsor the 1981 meetings, and they will be exhibiting on Monday and Tuesday, 10-11 August. Paper sessions, the featured symposium, business meetings, and most exhibits will be held on the third floor of the University Center.

Memphis is located in West Tennessee on the bluffs of the Mississippi River adjacent to Arkansas and Mississippi. Average rainfall for August is *ca.* 8 cm with daytime temperature ranging between 29 and 35°C. Metropolitan Memphis, with a population of over 900,000, offers a wide variety of entertainment, including museums, art galleries, amusement parks, and various nocturnal activities.

SSAR BUSINESS

PROPOSED AMENDMENT TO THE SSAR BYLAWS

The members of the Society for the Study of Amphibians and Reptiles are hereby notified of a proposal approved by the SSAR Board of Directors to amend Article VII, section 2 of the SSAR Bylaws (1970. *Journ. Herp.*, 4(1-2):98), which currently reads:

"Dues shall not exceed $15 annually."

to read:

"The amount of dues shall be established by the Board of Directors."

This proposed amendment will be on the agenda for discussion at the 1981 SSAR general business meeting at Memphis, Tennessee, in August 1981. A ballot on the amendment will be submitted by mail to the SSAR membership after the annual meeting in Memphis.

Respectfully submitted,
Joseph T. Collins
SSAR Secretary ●

1981 REGIONAL SOCIETIES MEETING

The 1981 Regional Herpetological Societies Meeting will be held Sunday, 9 August 1981 at Memphis State University in conjunction with the SSAR/HL meetings. A symposium, *Alien Amphibians & Reptiles: The Problem of Introduced Species*, will be part of this year's meeting. The second part will be a slide presentation. Contributors for the slide presentation are asked to bring 15 of their best slides and provide narration. The goal is to present photos of every North American species of amphibian and reptile, and as many other species as possible. Anyone interested in participating in the symposium or slide presentation is asked to contact: John C. Murphy, Regional Herp. Societies Liaison Committee Chairman, 201 Peerless Dr., Plainfield, IL 60544 before 1 May 1981. ●

OPEN LETTER FROM THE ASSOCIATION OF SYSTEMATICS COLLECTIONS

Dear George:

As you know, the Society for the Study of Amphibians and Reptiles is a member society of the Association of Systematics Collections. However, because relatively few institutions employing systematists have formal systematics collections (and hence relatively few are institutional ASC members), many systematists are unaware of ASC's existence and/or are unaware that ASC actively serves individuals in the systematics community as well as collection-oriented institutions. The reason for this is partly because ASC's name identifies the organization with collections and partly because ASC has failed to address itself directly to systematics beyond its member institutions.

Therefore, I am writing to request that the enclosed letter and accompanying announcement be published in your journal and/or newsletter. As you can see from the announcement, ASC currently is engaged in a variety of activities of vital interest to systematists in general. We would like to do more, and need feedback from various disciplines.

I must emphatically add that we will at no point endeavor to compete with discipline-oriented societies. However, most of ASC's activities span several disciplines and have proven to be of value to systematists at member institutions. Therefore, I am confident that these activities can be of value to colleagues elsewhere.

I thank you for the opportunity to present ASC to your colleagues, and hope that they will respond so that we may continue to serve the systematics community.

Sincerely,

Peter H. Raven
President

Dear Reader:

I am happy to have this opportunity to address the relationship between the Association of Systematics Collections and the needs of the systematics research community. The Association needs your input now more than ever,

as we begin preparation of a position paper on the long range needs of systematic biology.

The institutions that currently comprise the Association's membership maintain collections for the purpose of supporting research in the various disciplines of systematic biology. Decisions and national policies that affect these collections may have considerable impact on the research community and should not be made (or developed) without the participation of researchers.

A brief overview of activities the ASC has undertaken in the past is presented below. We are particularly interested in how these activities affect the research community, how they might be directed to better serve the systematics community as a whole, and the relevance of the activities to research programs.

Therefore, the ASC would appreciate feedback from systematists at member and non-member institutions concerning the problems faced in your research programs, and we would appreciate any suggestions you may have as to how we might help resolve these problems. We would also like to know about any discipline-oriented problems that you feel might be addressed through the ASC.

Also, the opportunity to share appropriate comments and suggestions with others in the systematics community through the **ASC Newsletter** would be most welcome.

It is our fervent hope that this letter and accompanying brief description of ASC activities will encourage exchange between the systematics community and ASC.

Sincerely,

Peter H. Raven
President

ACTIVITIES OF THE ASSOCIATION OF SYSTEMATICS COLLECTIONS

Representation.— ASC officers and staff have addressed congressional committees, federal agencies, and the Parties to the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) on a variety of matters directly affecting systematics collections and the systematists who use those collections. For example, the ASC has been responsible for obtaining a blanket exemption for international transfer of specimens of species listed in the appendices to CITES; contributed to the process that led to an exemption of public buildings housing systematics collections from federal temperature standards; testified before the Federal Council on the Arts and the Humanities concerning the needs of museums that maintain systematics collections; and testified before congressional committees on the proposed revisions in the Endangered Species Act. ASC is currently collaborating with the American Association of Museums in a lobbying effort designed to represent the needs of all types of museums.

ASC staff and consultants have successfully represented the needs of state and university systematics collections and their personnel to higher budgetary authorities when fiscal crises threatened the existence of those collections.

ASC maintains up-to-date information on the status of legislation affecting systematics *e.g.* government agency authorization and appropriation bills, regulatory actions, and species listings).

Funding.— Notice of most funding opportunities for systematists are circulated by the academic research administrations in their institutions. ASC maintains and makes available data on grants awarded by selected agencies for research programs and resource maintenance in systematics. ASC has assisted in locating funding for workshops, seminars, and short courses involving problems faced by systematists and systematics collections. ASC has repeatedly interfaced between the systematics community and federal funding sources other than NSF (*e.g.* Department of Energy, Environmental Protection Agency, Fish and Wildlife Service, and National Institutes of Health).

Interaction with member societies and provision of discipline-oriented services.— ASC has aided the production and dissemination of various publications on systematics resources generated by professional societies in eleven disciplines. ASC is cooperating on a contractual basis with the American Society of Mammalogists to maintain computer files of literature citations that are published as "Recent Literature of Mammalogy" in their journal and will be used for literature searches in the future.

Also in cooperation with the American Society of Mammalogists, the ASC maintains the *Checklist of the Mammals of the World.* ASC is developing a catalog of collections (domestic and foreign) containing specimens of mammal species listed as being "endangered" by the U.S. Endangered Species Act (files reference collection name, catalog numbers of specimens, and in some cases, locality data).

ASC cooperated on an at-cost basis with the North American Benthological Society in publishing *First Symposium on the Systematics and Ecology of Ephydridae (Diptera)* (1979. D. L. Deonier, Editor).

Center for Biosystematics Resources (CBR).— A registry of systematists and systematics collections is maintained by the ASC. This registry was originally designed for, and used extensively by, private industry and government agencies to locate biological specialists and/or collections. It is being refined to be of greater value to systematists seeking to locate other systematists or collections of special interest. As the data base expands, CBR will be able to profile the resources of the systematics community; *e.g.* personnel, funds, and facilities; and how these are distributed through time, according to discipline, and between institutions.

Systematics and the Law.— ASC maintains official lists of controlled species for both the federal government and Parties to the CITES. A liaison has also been established with representatives in each state responsible for maintaining lists of protected non-game species. This ensures that information about controlled species (federal, international, and state) is available to systematists via ASC publications and contact with our Law Project Biologist. ASC maintains up-to-date permit information for institutions and systematists working with controlled species.

ASC will soon publish *Pest Control in Museums: A Status Report (1980)* which contains chapters on federal statutes and regulations governing pesticide use, institutional liabilities, museum pest control procedures, and other aspects of the pest control problem. Appendices to this publication include pesticide descriptions, bibliography to pertinent literature, and an Annotation to Federal Pesticide Regulations.

Publications.— The *ASC Newsletter*, published six times each year, carries member institution and society profiles, funding opportunities, position announcements, legislative and curatorial information, equipment available for exchange, news and feedback from readers, book reviews, classified advertising, and other items of general interest to systematists. It is available free upon request in North America. Recipients outside North America must remit postage fees ($8.00 in U.S. funds) annually.

Miscellaneous.— ASC maintains an extensive bibliography of literature pertaining to "computerization" of collections and has prepared profiles on individual computer-oriented cataloging projects. ASC frequently serves as a clearinghouse for information on museum computerization projects and mid-range computer hardware.

ASC continually interfaces with various groups from outside the systematics community — private corporations, government agencies, and non-profit service organizations. ASC has coordinated workshops, seminars, and short courses involving problems faced by systematists. During the next year, the ASC through its Council on Curatorial Practices will formulate guidelines for the management and acquisition of voucher specimens, including suggested fee schedules.

A list of titles published by ASC may be obtained without charge by writing to the Association of Systematics Collections, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. ●

BEHAVIORAL OBSERVATION IN BULLSNAKES

An incident involving two bullsnakes *(Pituophis melanoleucus sayi)* was observed on 21 May, 1976, at approximately 5 P.M. by members of a University of Nebraska State Museum field party. The observation was made on the Kuhre Ranch road in extreme northern Brown County, Nebraska (SE¼, NE¼, SW¼, SW¼, Sec 32, T33N, R23W, USGS 15" Norden Quad).

The snakes were observed for approximately 25 minutes. Each was roughly one meter (39.37 inches) in length. Their bodies were very loosely intertwined and one individual had a firm grip on the right rear portion of the other's head (Figs. 1, 2, and 3). Neither animal acknowledged the presence of the observers.

During the observation, the biting snake was the more vigorous of the two, releasing its grip only once in order to grip the passive snake from the left. At irregular intervals, the biting snake would temporarily apply an additional loop against, but not around, the body of the other, well anterior of its vent. During the observation, the only movement offered by the passive snake was a very weak lashing of its body, perhaps in resistance to the actions of the vigorous snake. Blood was clotted upon the head of the passive snake and on the roadway.

As the snakes proceeded, there was no tight intertwining of bodies, nor elevation of anterior body portions of either snake, postures which are typical of ritualistic male combat in various snake species (Bogert and Roth, 1966; Shaw, 1951). No attempt at copulation was observed nor did the aggressive snake make any muscular undulations or twitches as described in courting males of *Pituophis m. melanoleucus* (Shaw, 1951). No third snake was obvious.

The two snakes were pulled from the roadway for their own safety, whereupon the biting snake took alarm and fled. Its sex is unknown. Nearly dead, the remaining snake was captured and found to be male upon eversion of hemipenes. Its stomach contained one, little-digested pocket gopher, *Geomys bursarius*. The macerated skeleton of the snake showed the parietal and prootic bones to be crushed and four vertebrae to be cracked. This damage, which may explain the passivity of the snake, is less extensive than one might expect had the animal been struck squarely by a vehicle, yet such crushing ability in the jaws of a colubrid is unlikely. It is conceivable that the injuries were caused by a glancing blow from the tire of a passing automobile.

Regrettably, the significance of this observation is ambiguous, for its inception was not observed, the sex of the vigorous snake is unknown, and the action was interrupted prior to its natural conclusion. However, three explanations for the observed behavior seem possible: 1) the behavior was combat; 2) the behavior was courtship, unusual, though, in that a male was in the passive role; 3) the interaction was an attempt by the aggressor to consume the injured snake.

Figure 1: Two individuals of *Pituophis m. sayi* loosely intertwined in roadway. Ascertained male has light ventral surface upwards. Ice pick, 20 cm long gives scale.

Figures 2 and 3: Close up views of the two snakes. Head of ascertained male in jaws of second bullsnake.

The body postures of the two snakes do not support either of the first two explanations, for they correspond poorly with the distinctive postures of combat and courtship described by Lowe (1948), Shaw (1948 and 1951), Lowe and Norris (1950), and Bogert and Roth (1966). Indeed, considering the estimated lengths of the snakes and conflicting reports of minimum adult length in *P. m. sayi* (36 in., Wright and Wright, 1957, and 50 in., Conant, 1975), the adult status of the individuals and their readiness to perform any vigorous combative or courtship activity is uncertain.

It is perhaps more probable that the aggressive individual was attempting to swallow the other snake, as ophiophagy (Porter, 1972) and even cannibalism (Klauber, 1947) have been reported in *Pituophis*. But while the aggressor physically may have been attempting to consume the injured snake, it is possible, given the observed behavior to be predation, that the incident was a natural response to the scent of the recently ingested pocket gopher on the head and mouth of the passive bullsnake.

ACKNOWLEDGMENT

I wish to express my thanks to Dr. J. D. Lynch, University of Nebraska-Lincoln for his review of this report.

ALBINISTIC NORTHERN WATER SNAKE IN ALABAMA

Hensley (1959) has previously reported 10 albino or albinistic northern water snakes, *Natrix sipedon*. Six of these specimens were born in the same litter of a normally colored individual from Michigan. These specimens were said to have the areas of dark markings flesh colored and a Virginia specimen was described as having a very faint pattern.

Figure 1. A juvenile albinistic *Natrix sipedon pleuralis* collected in Lee County, Alabama, in April 1976. Photo by Tom French.

A similar juvenile *Natrix sipedon pleuralis* (Figure 1) was captured on a warm, rainy night on a county highway, 4.5 air miles (7.2 km) south of Auburn, Lee County, Alabama, in April 1976. The eyes of this specimen were bright pink. The banded pattern was quite apparent but appeared a dark flesh color outlined in white and lacking melanic pigment. The areas between bands were a paler flesh color. This snake was kept in captivity for three months, and was fed small mosquitofish, *Gambusia affinis*. During this time, it never refused food or acted lethargic as Eells (1978) suggests some albinistic lizards and salamanders do. This specimen was photographed but not preserved.

STATUS OF THE OUTER BANKS KINGSNAKE, *LAMPROPELTIS GETULUS STICTICEPS*

The recognition of a subspecies is in part a matter of taste; no genuine consensus on the matter has emerged despite a plethora of discussion in the literature. Recently, Blaney (1979) has submerged the trinomial designation of the common kingsnake endemic to the Inter-Capes Zone of North Carolina's Outer Banks, claiming it shows "no characteristics unique enough to warrant the status of subspecies." Nevertheless, the suite of characters given as diagnostic by Lazell and Musick (1973) is unique. No specimen of nominate *getulus*, no specimen of *L. g. floridanus*, and no intergrade between those forms can match the combined characteristics of *sticticeps*.

Blaney has suggested a possible origin for *sticticeps* from an "intergrade population" between *getulus* and *floridanus*. It is not an origin with which we agree, but we admit conclusive evidence is currently lacking. Biochemical evidence should be sought. In any case, *sticticeps* is in no sense an intergrade between any other two forms today, either morphologically or geographically. If it originated as such, it has undergone dramatic differentiation from that stock. It is worth noting that none of the photographs provided by either Lazell and Musick (1973) or Blaney (1979) shows a dorsal interspace or the distinctive punctuations of *sticticeps*. The specimen shown by Blaney as Figure 1C is not a *sticticeps* and not from within the range of that subspecies.

Lampropeltis getulus sticticeps is easily identifiable at the 100 percent level within its range and qualifies as a valid subspecies in accord with the strictures elucidated by, for example, Simpson (1961). No one, of course, can be required to recognize it, or any other subspecies, but it is a most remarkable form behaviorally and ecologically (Lazell, 1979). It is demonstrably unique.

COURTSHIP BEHAVIOR OF MALE *TERRAPENE CAROLINA MAJOR* (REPTILIA, TESTUDINES, EMYDIDAE).

Except for that of *Terrapene carolina carolina* (Evans; 1953, 1968), the male courtship patterns of the subspecies of the eastern box turtle have been poorly described. Evans (1953, 1968) reported that a male *T. c. carolina* approaches a female but stops about 10 cm away. His legs are straightened (often one raised off the ground) and his head is held high. Next he circles around the female, biting her shell as he goes, or pushing her carapace with his head and shell a few degrees upon its axis and then biting it. The pushing-biting sequence is repeated several times. The male sometimes grasps the marginals of the female's carapace and drags her while he backs up. Rarely, the male will butt her carapace with his anterior plastral margin, ducking in his head just prior to impact. Next, he mounts her carapace from the rear and hooks his hind claws between her carapace and the closing plastron. When pinioned in this position, he leans back slowly until his carapace rests on the ground and then slides his hind feet forward until they lie medially to her hind feet. Coitus follows. Evans (1968) remarked that the mating of *T. c. major* takes place in shallow water, but in other respects resembles closely that of *T. c. carolina*.

Penn and Pottharst (1940) observed several aquatic matings of *T. C. major*, and thought higher air temperatures and high humidity were the most important stimuli to courtship and mating. Either stimulus alone was thought capable of initiating reproductive behavior. Some of their turtles had bite wounds on the cervical and first marginal scutes which they attributed to fighting among the males, and on females to the "post-mating caresses of their mates." After mating (and sometimes before) the males usually shoved the closed-up females with their heads.

My observations since 1969 on a captive, adult male *Terrapene c. major* (18.5 cm CL, 16.5 cm PL), while similar in some respects, have revealed differences from those courtship patterns reported above. During this period the male has courted several *T. c. carolina*, *T. c. triunguis* and *T. ornata* of both sexes, and males of *T. c. bauri*, *T. o. luteola*, *Clemmys insculpta*, and *Rhinoclemmys pulcherrima rogerbarbouri*. The only turtles kept with him that have not been courted were larger male *Geochelone elegans* and *Gopherus polyphemus*, and a female *Gopherus agassizii*. All the turtles were kept at low humidity in an indoor enclosure at temperatures greater than 20° C, and exposed to outside light. Increased photoperiod seemed to be the primary stimulus initiating courtship activity which occurred each year from March through June. During this time the *T. c. major* courted both day and night, and on land and in water. Individual attempts sometimes lasted for as long as three hours.

The behavior is always the same regardless of the sex involved, so it is thought to be courtship rather than just aggressive behavior. The male actively pursues his intended mate from behind with his head and neck fully extended forward (but not raised). First he places his nose close to (sometimes touches) the tail at the vent, hind legs and posterior carapacial marginals and appears to be smelling these. Occasionally he will bite these parts of the other turtle, but usually he moves to the side, and with head and neck still extended carefully "smells" the bridge, especially the inguinal area. After this he moves to a position where he can smell the head, neck

and forelegs of his intended mate, and then begins vigorously to bite these (the bite marks on Penn and Pottharst's females probably were due to such biting during courtship, not after mating). If he cannot reach the head region, due to the other turtle being closed-up or facing a wall, the male will ram and push the other turtle's carapace, sometimes for a distance of up to a meter. Finally, he moves posteriorly and attempts to mount in the manner described by Evans (1953).

That Evans (1953, 1968) and Penn and Pottharst (1940) should have failed to recognize some apparent olfactory behavior is a major deletion. The olfactory behavior of the male *T. c. major* is similar to that described by Eglis (1962) for the smelling of potential food by this subspecies. Pheromonal cues probably elicit courtship in aquatic turtles (Jenkins, 1979), and may account for the long pursuits of females by the males of terrestrial emydids and tortoises (Testudinidae) (Weaver, 1970; Auffenberg, 1978). Such a chase by male *Terrapene ornata* is described by Brumwell (1940) who also reported that a male of that species nosed about the lower carapacial margin of a female during courtship. Also, during the mating period, I have observed wild male *T. c. carolina* smelling the ground as they prowl through the woods, perhaps following a pheromone trail left by a female.

Terrapene carolina lack mental glands (Winokur and Legler, 1975), but perhaps pheromones are produced in undiscovered cloacal or inguinal glands (Rathke's glands of Ehrenfeld and Ehrenfeld, 1973).

STILL MORE ON *BIPES*

Naturalists in the state of Colorado, as well as elsewhere, have long been concerned with the mention of an encounter with "*Chirotes*" by members of the Long expedition to the Rocky Mountains in 1820. Drs. Richard G. Beidleman of Colorado College and T. Paul Maslin of the University of Colorado have been "on the scene," as it were, for 30-40 years, making periodical efforts to determine the bases for the report, and several graduate students at the University including Richard L. Holland and Geoffrey A. Hammerson, have likewise tried their hand at a solution. Considerable publicity resulted, at intervals, the most notable being an article that appeared in one of the local papers. All these efforts yielded only more anecdotes and speculation, hence were not recorded.

The revival of speculation on the subject in the formal literature of herpetology by Campbell (1980), however, calls for a "progress report" that is long overdue.

Taylor's casual dismissal (1938) of the Long expedition report was fully justified on the basis of knowledge at that time, for two reasons of both of which he was well aware. For one, the description in James' account, that "They were so active, that it was not without some difficulty that we succeeded in obtaining a specimen", is completely erroneous. *Bipes*, as Taylor knew from field experience in 1932 and later, is sluggish, secretive, no more difficult to catch — once discovered —than *Lumbricus*. The James description of behavior cannot possibly fit *Bipes*, which is neither constructed for nor inclined toward quick, elusive movements. On the contrary, the slender *Eumeces multivirgatus*, moderately abundant where the *Bipes* was reputedly found, does fit the description very well. The Bell account (1957) of the same journey does not mention "*Chirotes*." Secondly, amphisbaenids are exclusively tropical and subtropical reptiles, so far as is known; survival of any member of that suborder through the notoriously rigorous, protracted winters of northeastern Colorado defies credence.

Hence Taylor (*op. cit.*) was quite justified in rejecting the credibility of the James account of *Bipes*. Gans and Pappenfuss (1980) agree on similar grounds with that conclusion.

A haunting awareness remains, however, that such reputable zoologists as Say, James and Peale could scarcely confuse *Bipes* in hand with a *Eumeces*. The suspicion arises that the confusion concerned behavior only, that of *Eumeces* being transferred in memory to that of *Bipes*. Such confusion could possibly have been promoted by Thomas Say's ill health suffered through much of his travels in Colorado. Certainly the fact that the *Bipes* account had to be reconstructed from memory could have been a contributing factor in confusion.

The behavioral discrepancy can thus be accounted for with some credibility, but the climatic discrepancy remains a formidable hurdle to acceptance of the actual observation of *Bipes* on the Long expedition.

The record might remain in this very dubious, if not completely untenable state if there were no other grounds for acceptance. Dundee (1980) relates a disturbing anecdotal "record," and Dr. T. Paul Maslin also experienced two startling anecdotes supportive of the thought that *Bipes* occurs in northeastern Colorado. These were mentioned but not described by him (p. 72) in his 1959 summary of the Colorado herpetofauna.

On one occasion a well-educated janitor at Colorado State University in Ft. Collins, where Maslin taught at the time (in 1946), described in minute detail what could only have been a *Bipes* that he had discovered some years before on a farm he owned southeast of Ft. Collins. Shown a *Eumeces multivirgatus*, the janitor dismissed it at once, commenting that these skinks were common and well known to him, whereas the "two-legged lizard" was far different. Maslin was strongly of the opinion that no fabrication was involved, and that the observation was not based on *Eumeces*.

Shortly afterwards, a graduate student at CSU described in equally convincing detail an encounter with another supposed *Bipes* found under a rock on the west side of a hogback a few miles west of Loveland. She did know about the *Bipes* controversy, but the janitor did not. His awareness of the existence of such creatures had to have been solely through his own observations, unlike the situation in southeastern Arizona where most local residents are fully aware of the reputed occurrence there of *Bipes* and are only too eager to string panting herpetologists along with tales of encounters with the animals.

Nevertheless substantiation of the more recent Colorado reports remains elusive. Beidleman around 1955 circulated some 35 form letters, with a sketch of *Bipes*, to biology teachers, wildlife officers and others in northeastern Colorado where they might have encountered them, or were in a position to contact others who might have observed the animals, without any pertinent response whatever.

Thus on somewhat different grounds Maslin, Beidleman and ourselves have come to essentially the same conclusion as Campbell and Dundee — that *Bipes* does occur in extreme rarity in the sand belt of eastern Colorado and western Nebraska, or did so until very recently. Substantive proof remains to be obtained — a challenge to future naturalists that is likely to be even more frustrating than the search for the Loch Ness monster.

SEVEN NESTS RECORDED FOR LOGGERHEAD TURTLE *(CARETTA CARETTA)* IN ONE SEASON

On the night of 9 August 1979, a female loggerhead turtle was documented laying her seventh nest for the 1979 season on Little Cumberland Island (LCI), Camden County, Georgia. Although green turtles *(Chelonia mydas)* have been observed laying seven nests (Carr *et al.*, 1978) in a single season, the greatest number reported in the literature for a loggerhead has been five nests (Hughes, 1974). Worth and Smith (1976) suggested that one loggerhead in their study may have laid six nests and several instances of loggerheads nesting six times in a season have been recorded on Little Cumberland Island (Richardson, pers. comm.).

The loggerhead was tagged (Blue Rototags, GA0471 GA0472) while laying a nest on 19 May on the north end of Cumberland Island (CI) just south of Little Cumberland Island. She layed six additional recorded nests: 4 June (CI), 18 June (LCI), 2 July (CI), 15 July (LCI), 27 July (CI) and 9 August (LCI). The 1979 nesting season on the two islands extended from 12 May to 21 August. Since the mean inter-nest interval was 13.67 days (SE = 0.56 days), it is unlikely that additional nests were missed.

The fact that this female bore tag scars from a previous year plus her measurements (Carapace Length 103.5 cm, C. Width 97.0 cm, Head Width 21.5 cm; all measurements over the curve) indicate that 1979 was not the first nesting season for this turtle.

TECHNIQUES

INEXPENSIVE CONTAINERS FOR LARGE HERPETOLOGICAL SPECIMENS

It has always been difficult to store whole, large herpetological specimens (*e.g.*, turtles, crocodiles, large snakes, adult varanids, *etc.*). Museums have historically used various containers for this purpose; crocks, barrels, specially made large tanks of wood or fiber glass, stainless steel tanks, and extra large glass jars. In general, a container with a wide orifice but a limited volume permits easy retrieval of specimens in a collection where frequent retrieval and permanent storage are both major objectives. We have used stainless steel tanks and large glass jars extensively in the past. Their major disadvantages are the high cost of tanks (*ca.* $2.66 per liter of storage volume) and the narrow orifice (120-130 mm) and fragility of the glass jars.

In the last 10-15 years, museums have tried various "plastic" containers for specimen storage, particularly various kinds of covered garbage containers and buckets. Most of these containers fail because they are difficult or impossible to seal, they become grossly deformed when filled to capacity, and they crack unpredictably.

A completely satisfactory plastic container has been in use in the University of Utah turtle collections for approximately 5 years. This container is inexpensive and durable and seems ideal for most large specimen storage problems. This description is prepared chiefly because many curators are still unfamiliar with these containers.

The containers are Saturn® all plastic, open head, shipping pails (hereinafter "plastic buckets") (Figs. 1 & 3). Construction is of high density virgin grade polyethylene, about which the supplier writes, "this material is compatible with most chemical compounds such as acids, etc. *Exceptions:* solvents that are petrochemical derivatives such as benzene and toluene." The plastic buckets come in 1, 2, 3½, 4, 5, and 6 gallon sizes and cost $.81-$3.12 each in the western U.S. in January 1980. Each container is supplied with a wire carrying handle (including a plastic grip) and with a locking lid. The tight-fitting lids are available with or without gaskets.

Saturn® buckets are manufactured in the U.S. by Roper Plastics Inc., P.O. Box 63198, Los Angeles, California, 90063. Price per 5-gallon bucket in Salt Lake City, Utah (January 1980) with plain lid was $2.48 ($2.55 with poured gasket, $2.65 with O-ring gasket). An equivalent product is marketed by All Dispensing Supplies (P.O. Box 81, San Souci, N.S.W. 2291) in Australia at $2.76AUS per 5-gallon bucket.

Saturn® buckets seal tightly. If the opposing surfaces of lid and rim are clean and undamaged, a bucket can rest in any position without leaking. This tight seal can be achieved with any of the 3 kinds of lids mentioned. Lids are properly seated by applying simple force with the heel of the hand or with a rubber mallet. There is a characteristic resonant snapping sound when the lid seats itself. The lids can be easily and properly removed only with special tools. The Roper Opening Tool ($6.50) works on a pliers principle and is adequate (Fig. 2). We have

Fig. 1. Three kinds of containers used for large herpetological specimens at the University of Utah (glass jar, stainless steel tank -bottom, and Saturn® plastic buckets - on shelf at right and stacked on dolly in background. Note translucency and easily discernible fluid levels).

Fig. 2. Roper Opening Tool.

designed a simpler hook which fits under the edge of the lid without damaging the gasket (Figs. 3 & 4).

Use of these containers at U.U. has been entirely positive. We can detect no deterioration or change in the containers or their gaskets when used in the usual manner with solutions of alcohol and formalin. We also use the containers to fumigate bones with chloroform and as shipping containers (for which purpose they were originally made).

The plastic material used in construction has a soft surface texture and the entire bucket and lid are flexible enough to be deformed without breaking. The walls are translucent, permitting easy visual determination of internal fluid levels.

We use the 5-gallon size almost exclusively. Overall dimensions are: diameter 30.5 cm; height with lid 35.5 cm. When fully loaded these containers weigh approximately 20 kg and can be carried easily. They fit nicely onto open museum shelving without excess allowance for clearance. The lid is recessed and permits secure stacking. Full buckets can be stacked 4 high on a movable dolly (total

Fig. 3. Hook-type opening tool in use.

height ca. 147.5 cm) without deforming the bottom bucket. Empty buckets nest neatly. The low cost and durability of Saturn buckets permit carefree use for shipping and field work.

The disadvantages of plastic buckets are few and minor: they are not transparent and they cannot be opened properly without a special but simple tool. Their advantages, in summary, are as follows: tight seal; noncorrosible; practically unbreakable; stackable

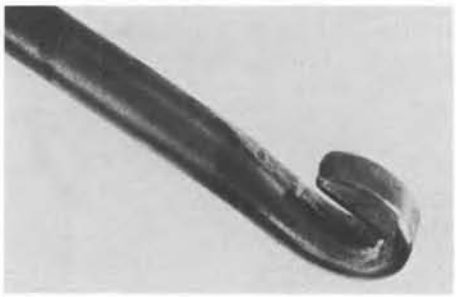

Fig. 4. Detail of hook-type opening tool.

when full and nestable when empty; large enough to accommodate most large herpetological specimens but small enough to be moved easily to provide easy access to contents; compatible with standard open shelving.

The cost of storage space per unit of volume in a plastic bucket (19 l, $2.56) is approximately 5% of that of a stainless steel tank (56.3 l, ca. $150.00).

Mr. Darrell MacBeth (Industrial Container and Supply Co., Salt Lake City) provided samples and information used in the preparation of this paper.

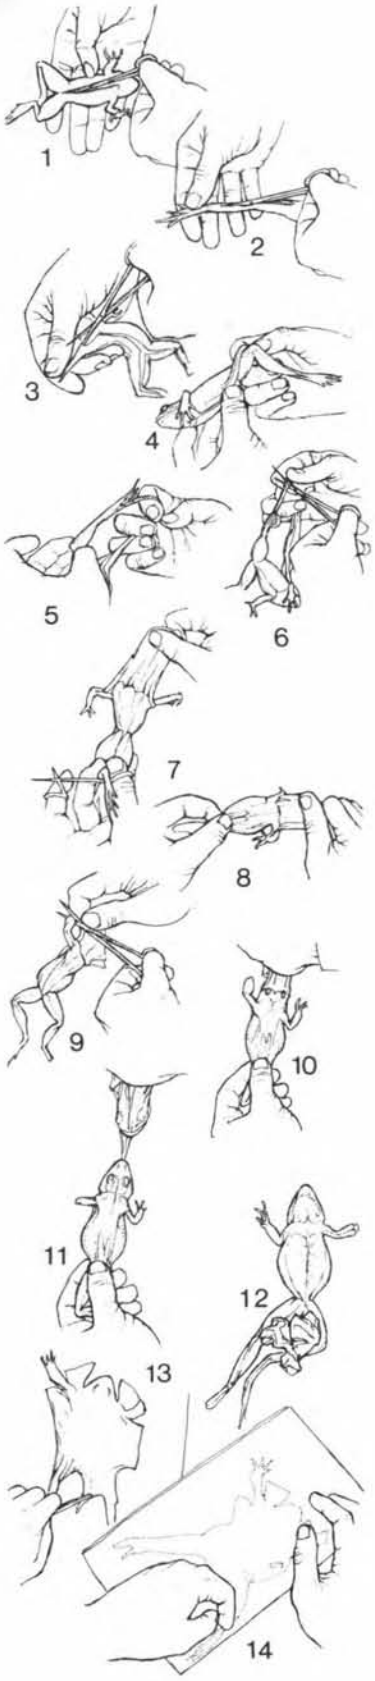
PRESERVING ANURAN SKINS BY DRYING

The preparation of amphibia for systematic study as dried skins was introduced by Kincaid (1948) and Juszczyk (1952), but has only been used, to my knowledge, by Turner (1959) in his study of variation in *Rana pretiosa* in Yellowstone Park, Wyoming, and by me (Schueler, 1973, 1979).

Juszczyk (1952) and Turner (1959) dried the skins on glass in the open air, a procedure that requires laboratory facilities and makes removal of the dried skin difficult. Kincaid (1948; cited by Cook, 1965) floated skins onto paper to which they adhered as they dried, so that the paper was warped as the skin shrank. In a notice of geographic variation in *Rana sylvatica* in northern Ontario I mentioned the drying of skins between waxed paper in a plant press (Schueler, 1973); this note describes this method of preservation and some attributes which can be assessed on dried skins which may be of interest in studies of variation.

PREPARATION OF SKINS



Juszczyk (1952) killed amphibia by destroying the base of the skull and the upper spinal column with scissors, a procedure that is not satisfactory if the skeleton is to be preserved; Turner (1959) used chloretone or dilute formalin. I find that color is well preserved if frogs are killed by over-anesthesia with dilute ethyl or isopropyl alcohol. I cut the skin with scissors along the ventral midline of the frog from the pectoral girdle to the vent (Figure 1) and along the ventral midlines of the legs. I strip the skin from the frog (Figures 5-11) leaving one hand and one foot on both the skin and on the carcass (by cutting through the joints; Figures 6 & 9). The skin is less likely to tear as it is pulled from the head if the midventral incision is not extended to the throat until the skin is removed. I rinse any blood or dirt from the skin in water, and keep it wet until spreading it (Figure 12). The skin is spread on half of a sheet of waxed paper (Figure 13). A thin paper label will stick to the outside of a smooth skin or to the flesh side of a rough skin (such as *Bufo*; thicker paper is more likely to work loose from the skin with bending and humidity changes). I then fold the waxed paper over the skin, smooth out wrinkles and air bubbles (Figure 14), and dry it between blotters in a plant press.

Skinning is most rapid if sharp pointed scissors are used, and spreading is facilitated by a hard, rounded object such as the single end of forceps or a pen cap. With experience, it takes little more than a minute to skin a 40-80 mm *Rana*, and a little less than a minute to spread the skin on the waxed paper. Larger and smaller specimens take longer to prepare, as do taxa with lumpy skins or skin adherent to bone. A novice skinner may take 15 minutes or longer to deal with a specimen. If dry blotters are changed twice, the skin will be dry in 24 h at 20-25° C.

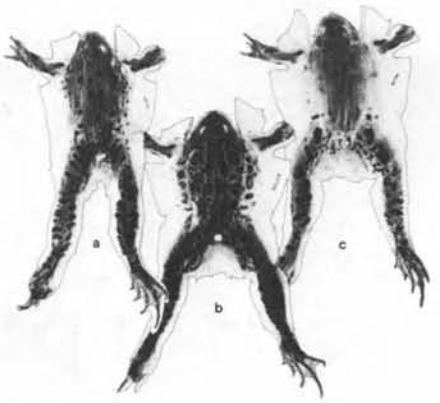
When the skin is dry it can be removed from the waxed paper by first peeling the paper from the one side of the skin and then drawing the paper over the sharp edge of, *e. g.*, a table, so that the paper pulls off the skin from below. Newly dried skins will curl, and should be kept lightly pressed until they reach equilibrium with ambient humidity. Some skins of *Rana pipiens* are shown in Figure 15. For storage, I glue skins, by the hand left on the skin, to 100% rag content typing paper with a permanent white glue. Rubber cement will discolor the skins (Turner, 1959), and will eventually fail. Collection data should be written on the paper, as the field labels may come unstuck from the skins after a lapse of years. Skins of *Rana pipiens* prepared by Joyce C. Cook and C. Bruce Powell in 1963 (National Museum of Natural Sciences 19405) show no apparent signs of deterioration or of separating from the paper on which they were dried.

ATTRIBUTES OF DRIED SKINS

All pigmentary colors are initially preserved by drying (Juszczyk, 1952), though the structural green of anurans is lost. I have found that after 9 years, the ventral orange of *Rana palustris* and *Hyla versicolor* is lost, and that the ventral yellow of *Rana sylvatica* and *R. clamitans* is somewhat faded. Dermal secretory glands are often conspicuous by their translucency in the dried skin. Colors and color patterns can be measured directly or by comparison with standards, and relatively undistorted linear and area measurements

Stages in the skinning of a Northern Leopard Frog (*Rana pipiens*; see text).

can be made of dorsal pattern elements and of glandular structures such as the warts of toads and the glandular ridges of leopard frogs. The dispersion of pigment in melanophores and other pigment cells is very well preserved, and can be examined in detail by microscopy. The bones of the feet can be measured in the skin, and the rest of the skeleton is also available, as are all of the internal organs and musculature.



I have made linear measurements with a plastic ruler and area measurements with a grid of points in clear photographic film while the skin was illuminated by reflected or transmitted light (Schueler, 1979), but the two-dimensional character of the skins predisposes them to use with digitizers, reflecting photospectrometers, and other semi-automatic methods of measurement.

Making a three-dimensional skin into a two-dimensional object necessarily distorts the surface, but such shrinkage and buckling as occurs seems to leave the dorsal skin relatively undistorted. In 16 *Rana* skins on which I measured the distance from the pineal spot to the posterior limit of the dorsal lymph sac (SKIN LENGTH) both when the skins were wet (in waxed paper) and a month later when they were dried (and removed from the paper) the two measurements were correlated at r=0.97, and there was an average of 4.7% shrinkage. Dried SKIN LENGTH is highly correlated with other measures of body size (Snout-vent length, cube root of body mass) among 30 male (r's=.98) and 40 female (r's=.99) *Rana pipiens* from Carleton Co., Ontario, collected in August 1979. In a random sample of 100 male *R. pipiens* from the specimens listed in Schueler (1979), on the other hand, SKIN LENGTH and the cube root of body mass are less correlated (r=0.83), but these frogs were collected in many places over several years, and the error varianace (21.5% of the total) may be due more to the measurement of "size" as mass (because of differences in the physical condition and hydration of the frogs and among the scales used) than to any "true" lack of correlation between SKIN LENGTH and "size."

Three analyses from a study of geographic variation amont 828 *Rana pipiens* skins provide some evidence that the skins are presrved with little (or at least uniform) distortion: the high loadings (0.92-0.96) of characters which measure parts of the skin (rather than pigmentation or dermal glands) on their first principal component (Table II-10 in Schueler, 1979), the absence of any effect of the circumstances of preparation (fresh or frozen specimens; slower or faster drying) on variation in pigmentation and dermal glands (Table II-2 in Schueler, 1979), and the high correlations between patterns of geographic variation in the skins with that found in fluid-preserved specimens (Table IV-1 in Schueler, 1979).

ACKNOWLEDGMENTS

These methods were developed for a thesis at the University of Toronto Department of Zoology (Schueler, 1979). I have been generously supported by the National Engineering and Research Council through their grants to J. D. Rising and a fellowship at the National Museum of Natural Sciences. I thank Aleta Karstad for drawing Figures 1-14 and thank her and Francis R. Cook for reading the manuscript.

Skins of spotted (FWS 3271) and apparent *burnsi* (FWS 3258) and *kandiyohi* (FWS 3288) *Rana pipiens* from the tip of Long Point, Norfolk County, Ontario, September 1972 (deposited in the National Museum of Natural Sciences but not yet catalogued).

Herpetology of Brazil

COMPRISING THREE BOOKS BY J. B. VON SPIX AND J. G. WAGLER
TOGETHER WITH A NEW INTRODUCTION BY P. E. VANZOLINI (SAO PAULO)

about 400 pages (including 98 plates); 8 1/2 by 11 inches; index

IN 1817 Johann Baptist von Spix and his colleague Karl-Friedrich-Philipp von Martius, a botanist, set out from Bavaria on a three-year exploration of Brazil. Besides collections of plants and other animals, those of amphibians and reptiles provided the most comprehensive and important early survey of the herpetology of Brazil and, indeed, of all of South America. Some 155 species were described, most of them newly discovered, as well as first descriptions of such familiar genera as *Bothrops, Micrurus, Kinosternon* and *Caiman* among others. All species were beautifully illustrated in detailed, full-page plates, one of which is reproduced in color.

This reprint edition includes the original volumes (first published in Munich, 1824-25) plus an extensive new introduction by Professor Vanzolini which gives an itinerary for the Spix-Martius expedition (with map) through the Atlantic forests, the caatingas of northeastern Brazil and up the Amazon River to the Peruvian border. In addition, there is an historical discussion of the expedition; tables of species names with modern equivalents to bring the nomenclature up to date; a detailed review of the type localities; and an announcement of the rediscovery of Spix's and Wagler's type specimens in Munich and Leiden.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Geographic Distribution

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of the range of a species, and thereby permit a more significant interpretation of the biology of same.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles** , Collins, Huheey, Knight and Smith, 1978), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address).

Some further comments. This geographic distribution does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged).

Please submit new geographic distribution records in the **standard format** only to Joseph T. Collins, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. Short manuscripts are discouraged, and are only acceptable when data **cannot** be adequately presented in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

ANURA

RANA SYLVATICA (Wood Frog). USA: ARKANSAS: Pope Co: NW 40 acres of NW ¼ sec. of sec. 34, R19W, T12N. 11.7 km SE of Pelsor. 26 June 1979. L. Lewis. Arkansas Tech University Collection. No. 235. Verified by G. Turnipseed. County record for Pope County.

Submitted by **GLYN TURNIPSEED,** Department of Biology, Arkansas Tech University, Russellville, Arkansas 72801. ●

SAURIA

ANOLIS CAROLINENSIS CAROLINENSIS (Green Anole). USA: TEXAS: Navarro Co: collected within the city limits of Corsicana. 28 March 1980 by Cary Crum. Verified by Thomas Vance. Navarro College (NC 1980.3. 28.1L). First recorded for Navarro County and extends known range approximately 25 km W of the previously recorded locality of Henderson County (Raun and Gehlbach, 1972, Dallas Mus. Nat. Hist. Bull. 2:1-1). The specimen is a female with a broken tail.

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: St. Lucie Co: Hutchinson Island, Fort Pierce, Hernando Avenue. 10 September 1978. S. Myers and B. Hutchinson. Verified by P. Meylan. Florida State Museum (UF 44103-44106). Found on houses and shrubs. This locality lies 82.6 km N of Riviera Beach population (King, 1960, Quart. J. Fla. Acad. Sci. 23(1):71-73) and 25.4 km S of Vero Beach record (Myers, 1978, SSAR Herp. Review 9(3):107). This series represents the first voucher specimens from St. Lucie County including Hutchinson Island. Previously observed on mainland Ft. Pierce (Myers, 1978, SSAR Herp. Review 9(3):107).

Submitted by **STEVEN MYERS,** Department of Herpetology, Fort Worth Zoological Park, Fort Worth, Texas 76110. Present address: The University of Texas Health Science Center at Dallas, Division of Comparative Medicine, Animal Resources Center, Dallas, Texas 75235 ●

EUMECES ANTHRACINUS PLUVIALIS (Southern Coal Skink). USA: Arkansas: Pike Co: collected within a picnic area of Lake Greeson, 2 km W Daisy. 9 September 1979. Thomas Vance. Verified by Thomas Vance, Navarro College, Corsicana (NC 1979.9. 30.11L). First record for Pike County which partly fills a hiatus within the southwestern part of its range. (Dellinger and Black, 1938, Occ. Papers Univ. Arkansas Mus. 1:2-47; Dowling, 1957, Occ. Papers Univ. Arkansas Mus. 3:3-51; McAllister, 1980, Herp. Rev. 11(4):115; and Smith and Smith, 1952, Univ. Kansas Sci. Bull. 34(11):679-694). This specimen was found in damp and decomposing leaf litter.

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

EUMECES FASCIATUS (Five-lined Skink). USA: OHIO: Erie Co: 1 km N Castalia. 13 August 1980. Gordon W. Schuett and Fred Kraus. Verified by G. W. Schuett and F. Kraus. University of Michigan Museum of Zoology (UMMZ 170388 and 170389). First records for Erie County (see Conant, R. 1951. Amer. Midl. Nat. 33:1-284.). An adult male and female were collected beneath a railroad tie in a disturbed field next to State Route 269. Three other individuals were seen at this locality that day. This skink has also been found by us in nearby Resthaven Wildlife Area in Erie County.

Submitted by **GORDON W. SCHUETT** and **FRED KRAUS,** Department of Biology, University of Toledo, Toledo, Ohio 43606, and, University of Michigan Museum of Zoology, Ann Arbor, Michigan 48109. ●

XANTUSIA VIGILIS VIGILIS (Desert Night Lizard). USA: CALIFORNIA: Fresno Co: 14.8 km S on BLM access road off Little Panoche Road at Mercy Hot Springs, R11E, T14S, Sec. 32. 11 September 1978. J. S. Kaufmann and K. Tollestrup. Verified by H. Greene, University of California, Berkeley. Museum of Vertebrate Zoology, U. C. Berkeley (MVZ 172250). This is the first record for Fresno County. Specimen found at the base of a dead *Yucca whipplei.* This plant appears to be restricted to the upper west-facing slopes of the Panoche Hills.

SERPENTES

AGKISTRODON CONTORTRIX CONTORTRIX (Southern Copperhead). USA: ARKANSAS: Newton Co: collected 19 km W Jasper. 24 June 1980 by Thomas Vance. Verified by Thomas Vance. Navarro College (NC 1980. 6.24.1S). First record for Newton County which partly fills the area between most surrounding Arkansas counties (Dellinger and Black, 1938, Occ. Papers Univ. Arkansas Mus. 3:3-47, and Dowling, 1957, Occ. Papers Univ. Arkansas Mus. 3:3-51). The neck of this specimen is partly mutilated due to it being injured and the overall color pattern is darker and more intense than southern representatives of this subspecies.

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

COLUBER CONSTRICTOR PRIAPUS (Southern Black Racer). USA: ARKANSAS: Pike Co: collected 7 km E Athens on Hwy 84. 7 April 1980 by Thomas Vance. Verified by Thomas Vance. Navarro College (NC 1980. 4.7.2S). First record for Pike County and partly fills the area of the southern part of its range between most surrounding counties (Dellinger and Black, 1938, Occ. Papers Univ. Arkansas Mus. 1:3-47, and Dowling, 1957, Occ. Papers Univ. Arkansas Mus. 3:3-51).

This specimen is a juvenile with typical markings of the subspecies *constrictor*, and was collected at 1115 hours as it was crawling across the road.

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: TEXAS: Navarro Co: collected 0.8 km S Mildred and 9.6 km S Corsicana. 10 October 1980 by Randall Roper. Verified by Thomas Vance. Navarro College (NC 1980.10.6.1S). First record for Navarro County and partly fills the area within its east Texas range (Raun and Gehlbach, 1972, Dallas Mus. Nat. Hist. Bull. 2:1-61). This is a juvenile specimen with typical characters exhibited by this taxon (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston).

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

ELAPHE OBSOLETA LINDHEIMERI (Texas Rat Snake). USA: TEXAS: Freestone Co: Collected within the city limits of Donie. 21 September 1980 by Jill Pickens. Verified by Thomas Vance. Navarro College (NC 1980.9.21.1S). First record for Freestone County which partly completes its known range in east-central Texas (Raun and Gehlbach, 1972, Dallas Mus. Nat. Hist. Bull. 2:1-61 and Vance, 1980, Bull. Chicago Herp. Soc. 15(3):70-76). This specimen is a juvenile with typical characters of this taxa (Conant, 1975, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston).

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

HETERODON PLATYRHINOS (Eastern Hognose Snake). USA: ARKANSAS: Searcy Co: collected 12 km NNW Marshall on the Buffalo River, Buffalo National River. 29 June 1980 by Macon Edwards. Verified by Thomas Vance. Navarro College (NC 1980.6.29.1S) soon to be relinquished to the Buffalo National River Museum, Harrison, Arkansas. First record for Searcy County and partly fills the area for the northern part of its Arkansas range between most of the surrounding counties (Dellinger and Black, 1938, Occ. Papers Univ. Arkansas Mus. 1:3-47 and Dowling, 1957, Occ. Papers Univ. Arkansas Mus. 3:3-51). This specimen is a juvenile which was caught as it was swimming along the shore of the Buffalo River.

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

HYPSIGLENA TORQUATA (Night Snake). MEXICO: Baja California del Norte: Isla La Ventana, 28°55' N, 113°32' W. 30 April 1980. Allan W. Smits. Verified by Darrel Frost and Lawrence Hunt. Specimen is mummified, rodent chewed, lacking head (KU 186728). Represents first record of this genus from the island.

Submitted by **ALLAN W. SMITS,** Department of Physiology and Cell Biology, University of Kansas, Lawrence, Kansas 66045. ●

STORERIA DEKAYI (Brown Snake). USA: OHIO: Ottawa Co: Middle Bass Island. 24 June 1979. Gordon W. Schuett and Fred Kraus. Verified by G. W. Schuett. University of Michigan Museum of Zoology (UMMZ 170387). First record for Middle Bass Island (see Langlois, T. H. 1964. Ohio J. Sci. 64(1):11-25.). This snake is abundant on Middle Bass, and has recently been collected by us on North Bass Island.

Submitted by **GORDON W. SCHUETT** and **FRED KRAUS,** Department of Biology, University of Toledo, Toledo, Ohio 43606, and University of Michigan Museum of Zoology, Ann Arbor, Michigan 48109. ●

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). USA: ARKANSAS: Marion Co: collected *ca.* 17 km SE Yellville on a dirt road near the Buffalo River, Buffalo National River. 29 June 1980 by Macon Edwards. Verified by Thomas Vance. Navarro College (NC 1980.6.29.2S). First record for Marion County and partly fills the area for the north-central part of its Arkansas range (Dellinger and Black, 1938, Occ. Papers Univ. Arkansas Mus. 1:3-47 and Dowling, 1957, Occ. Papers Univ. Arkansas Mus. 3:3-51). This specimen is a DOR and was somewhat decomposed at the time it was collected, but it is still identifiable.

Submitted by **THOMAS VANCE,** Biology Department, Navarro College, Corsicana, Texas 75110. ●

ELEUTHERODACTYLUS BRANSFORDII (COPE): AN ADDITION TO THE FROG FAUNA OF HONDURAS

Among the materials collected by Arden H. Brame, Jr. in Honduras, during 1969 and not available for inclusion in Meyer and Wilson's (1971) account of Honduras amphibians is a small frog (LACM 45200) completely overlooked during the intervening years. The individual is a juvenile female *Eleutherodactylus,* 15.5 mm in standard length, taken from Departamento de Olancho: 0.8 km SE San Jose de Rio Tinto, approx. 14 km NE Catacamas at an elevation of 330 m. It was collected February 20, 1969.

The example agrees in every respect with specimens of *Eleutherodactylus bransfordii* as described by Savage and Emerson (1970) and in direct comparison to material from Costa Rica and Nicaragua. This species cannot be confused with any other form in Mexico or Central America because of the combination of rudimentary disks on fingers (no disks on fingers I-II) and toes, no toe webbing, an inner tarsal fold and numerous strongly developed small pungent plantar tubercles. This example has the following character formula, according to the system of Savage and Emerson (1970), M Z_1 C X B P R: Morph II.

The specimen is the first record for Honduras and comes from a locality approximately 170 km NE of the previously northernmost record for the species in the Bonaza mining area (200-300 m) of Departamento de Zelaya, Nicaragua. The site of capture is in a narrow ecotone between lowland moist forest and premontane wet forest according to the Holdridge (1967) terminology. It probably lies in what is essentially a gallery forest predominated by vegetation of the latter type. The few records of this species from eastern Nicaragua as compared to its ubiquitous presence at lowland sites in Atlantic slope Costa Rica suggest that this frog does not occur in the lowland pine savanna areas of Nicaragua and Honduras. From southeastern Nicaragua northward the species is to be expected only along the margins of the Honduras-Nicaragua uplands in especially humid situations and gallery forests. The lack of collecting in such places in eastern Honduras, because of their inaccessibility, probably explains the absence of other records of the republic. Three other species of *Eleutherodactylus (mimus, noblei* and *ridens)* that are relatively common in Atlantic slope Costa Rica and adjacent southeastern Nicaragua, are similarly known from only a single locality in eastern Honduras (Meyer and Wilson, 1971). The *E. mimus* and *E. noblei* records are also from Departamento de Olancho from habitats that seem similar to that at the Rio Tinto locality.

A RANGE EXTENSION AND LOW ELEVATIONAL RECORD FOR THE ARIZONA RIDGE-NOSE RATTLESNAKE *(CROTALUS W. WILLARDI)*

The Arizona ridgenose rattlesnake *(Crotalus w. willardi)* is a montane subspecies of limited distribution in southeastern Arizona, having been recorded only from Carr and Ramsey Canyons in the Huachuca Mountains and from the Santa Rita Mountains. Specimens have been observed at elevations ranging from 1700 m to over 2740 m (Stebbins, 1954; Klauber, 1972) in plant associations dominated by Arizona white oak *(Quercus arizonica)*, big-tooth maple *(Acer grandidentata)*, New Mexican locust *(Robinia neomexicana)*, Douglas fir *(Pseudotsuga taxifolia)* and white fir *(Abies concolor)* (Wright and Wright, 1975). Lowe (1964) states that this rattlesnake is present from the Transition Zone to the Upper Sonoran, and is most commonly found on conifer forest floors. Shaw and Campbell (1974) have suggested that this snake may favor canyon bottoms dominated by deciduous trees such as maple, oak and ash.

An adult male *C. w. willardi*, measuring 550 mm in length, was observed seven kilometers west of Parker Lake, Cochise County, Arizona, in the rolling foothills southwest of the Huachuca Mountains. The snake was found coiled under a piece of bark near a decomposing oak log along a south-facing slope of a small tributary canyon of Brushy Canyon. Dominant vegetation included Arizona sycamore *(Platanus wrightii)*, Mexican pinyon *(Pinus cembroides)*, one seed juniper *(Juniperus monosperma)*, Arizona ash (*Fraxinus velutina*), Emory oak *(Quercus emoryi)* and Mexican blue oak *(Quercus oblongifolia)*. This plant community has been described as pine-oak woodland by Lowe and Brown (1973), also exhibiting characteristics of the deciduous woodland community. Elevation is 1600 meters.

The presence of this subspecies at a previously unrecorded elevation and in a characteristic southern oak-juniper community raises the possibility that it may be more widespread than previously suspected, and certainly not as restricted to higher elevations and more montane habitats. Canyon systems in this area, with their lush vegetation, thicker canopy and rockier substrate may provide a means for dispersal from isolated mountain ranges into more arid, less habitable environments.

HERPETOLOGICAL RECORDS FROM A RELICT PRAIRIE IN OHIO

Killdeer Plains is a relict prairie in northwestern Ohio that developed during the xerothermic period following the last glaciation (Sears, 1942, Bot. Review 8:708-736). The original prairie was 30,000 acres, but due to intensive farming, only 7,000 acres remain and are contained primarily in the Killdeer Plains Wildlife Area, Wyandot County (7 km E Marseilles). We recorded 16 species of reptiles and amphibians during the course of a field study on *Thamnophis radix* (an endangered species in Ohio which is isolated, 483 km E of the rest of this species' distribution; Conant, Thomas, and Rausch, 1945, Copeia 1945:61-68) and *T. sirtalis*. Four of these species are records for Wyandot County and supplement Conant (1951, The reptiles of Ohio, Univ. Notre Dame Press). Individual specimens are in the Ohio State University Museum of Zoology (uncatalogued), unless otherwise stated.

Storeria occipitomaculata (Redbelly snake). On County Road 75 between CR 123 and CR 103. 2 October 1979. L. Reichenbach and N. Reichenbach. 5 DOR specimens. New Ohio county record and the second record for the till plains physiographic region in Ohio, 95 km SW of nearest record. A third isolated locality in the sparsely occupied area (W Ohio, E Indiana, N Kentucky) of this species distribution (Conant, 1975, *A Field Guide to Reptiles and Amphibians of Eastern and Central North America*, Houghton Mifflin, Boston).

Storeria dekayi (Brown snake). On CR 75 between CR 123 and CR 103. 2 October 1979. L. Reichenbach and N. Reichenbach. 10 DOR specimens. New Ohio county record, 39 km SW of nearest record.

Clonophis kirtlandi (Kirtland's snake). Pond #6. 4 September and 16, 20 October 1979. F. Dulin, M. Brown, G. Baker, J. Kinney, L. Reichenbach, G. Dalrymple, and N. Reichenbach. 9 specimens (7 adult, 2 juv.). New Ohio county record, 18 km NW of nearest record.

Chelydra serpentina (Common snapping turtle). Pond #6. 26 May 1978. W. Nichols and N. Reichenbach. Released at capture site. New Ohio county record, 27 km NE of nearest record.

A PACIFIC LOGGERHEAD CAPTURED OFF CALIFORNIA'S NORTHERN CHANNEL ISLANDS

A small Pacific loggerhead, *Caretta caretta gigas*, was captured in waters near Santa Cruz Island, California, on 15 March 1978. The encounter occurred three nautical miles off Valley Anchorage at 33° 56' N and 119° 39' W during a Bureau of Land Management Cetacea Survey.

The turtle, observed floating quietly at the surface of the water, was captured and brought on board the survey vessel, and was identified as a young female Pacific loggerhead. Straight line measurements of the keeled carapace were 457 mm (17.9 inches) in length and 381 mm (15.0 inches) in width. Approximate weight was 8.6 kg (18 pounds). A single species of barnacle and three small crabs were the only commensals associated with the turtle. These organisms were removed and preserved for specific identification.

Several investigators have reported the presence of *Caretta caretta gigas* in the waters of Southern California and Baja California, Mexico (Shaw, 1947; Caldwell, 1962; Marquez, 1969), but the loggerhead has not been previously reported this far north in the Southern California Bight. This record represents a northern extension of the range of the species on the Pacific coast.

HERPETOLOGICAL RECORDS FROM CENTRAL AND NORTHEASTERN ARIZONA

During the past 2 years, the Bureau of Land Management, Department of the Interior, Phoenix District, has been conducting herpetological inventories in areas from Phoenix, north to the Prescott National Forest and Wickenburg, northwest to Kingman.

Listed below are records that have been determined to be range extensions. Voucher specimens are on file at the Phoenix District herpetological museum unless otherwise noted. Vegetative associations listed are based on Brown and Lowe (1974).

ANURA

Bufo alvarius—Mohave County, Arizona, ca 3,200 ft. Alamo Spring, 15 km E Signal, T13N, R12W, SE, Sec. 9, Arizona Upland, 13 July 1977, KBJ 3314 Extends range WNW 100 km from that reported by Hahn and May (1972). Not collected.

Bufo woodhousei—Mohave County, Arizona, ca 1,600 ft. Big Sandy River, 10 km S Wikieup, T14N, R13W, NW, Sec. 12 Mesquite Bosque, 30 May 1979, BLM 2400 Extends range established by Stebbins (1966) by 150 km to the northwest.

TESTUDINES

Kinosternon flavescens—Mohave County, Arizona, ca 1,860 ft. In canal on Big Sandy River, 3 km S Wikieup, T16N, R13W, SE, Sec. 35, Mesquite Bosque, 26 March 1979, BLM 2378 Extends records 325 km of those cited by Iverson (1978)

SAURIA

Cnemidophorus velox—Mohave County, Arizona, ca 5,300 ft. Hualapai Mountains—Blue Tank Wash, 40 km NW Wikieup, Arizona T19N, R15W, SW, Sec. 33, Interior Chaparral (5 records), 28 September 1978, 12 October 1978 and 11 June 1979, BLM 2192, 2209, 2261, 2270, 2401 Extends range established by Stebbins (1966) 125 km to the west.

Cnemidophorus exanguis—Mohave County, Arizona, ca 4,700 ft. Hualapai Mountains, off Peacock Mountain Road, 26 km ESE Kingman T19N, R15W, SW, Sec. 12, Interior Chaparral, 14 May 1979, BLM 2402 Extends distribution 100 km (Stebbins, 1966).

Eumeces gilberti arizonensis—Mohave County, Arizona, ca 4,600 ft. Hualapai Mountains, 15 km S Kingman, T20N, R16W, SE, Sec. 10 Pinyon-Juniper-Interior Chaparral integrade (4 records), 14 May 1979, (3) 22 May 1979, BLM 2403-2406 Additional records by legal: T19N, R15W, SE, Sec. 12; T19N, R15W, NE, Sec. 32; T16N, R15W, NE, Sec. 15; T16N, R15W, NW, Sec. 24 An uncommon lizard found in Interior Chaparral, Desert Grassland, and Mixed Broadleaf Riparian of the Hualapai Mountains, Bozarth and Goodwin mesas, and Burro Creek, Santa Maria and Big Sandy River drainages. Extends record by Medica and Vitt (1974) 100 km to the northwest.

Cophosaurus texana—Mohave County, Arizona, ca 4,600 ft. Cerbat Mountains, 10 km NW Kingman, T22N, R17W, NW, Sec. 28, Mohave Desertshrub, 13 May 1977, BLM 5001 Extends range 50 km to the NNW (Stebbins, 1966).

Sceloporus clarki—Yavapai County, Arizona, ca 2,100 ft. Santa Maria River, 85 km SE Wikieup, T12N, R9W, NE, Sec. 10, Mesquite drainage, 10 October 1979, BLM 1710 Extends distribution 100 km to the WNW (Stebbins, 1966).

Sceloporus undulatus—Mohave County, Arizona, ca 7,045 ft. Hualapai Mountains, 25 km SSW Kinghan, T19N, R15W, SE, Sec. 5, Pineoak, 28 September 1978 BLM 2186 The most common lizard in the Hualapai Mountains above 4,500 ft. Extends range of this species 50 km WSW (Stebbins, 1966).

Xantusia vigilis vigilis—Mohave County, Arizona, ca 4,000 ft. Southern end of Hualapai Mountains, 12 km W Wikieup, T15N, R13W, SE, Sec. 7, Juniper w/Yucca *elata* and *Nolina* sp., 18 September 1978, (3 records) BLM 2369-2371 Extends distribution ENE 50 km of the Yucca Arizona area (Stebbins, 1966).

Xantusia arizonae—Mohave County, Arizona, ca 4,700 ft. Hualapai Mountains, off Peacock Mountain Road, 26 km ESE Kingman, T19N, R15W, SW, Sec. 12, Interior Chaparral, 3 May 1979, BLM 2407 Extends range 75 km to the WSW (Stebbins, 1966).

SERPENTES

Tantilla planiceps atriceps—Mohave County, Arizona, ca 1,860 ft. Big Sandy River 3 km S Wikieup, T16N, R13W, SE, Sec. 35, Mesquite Bosque, 29 May 1979, BLM 2408 Extends the record of Hahn and May (1972) by 60 km to the northwest.

Leptotyphlops humilis—Mohave County, Arizona, ca 2,240 ft. 14 km SSE Wickieup, T15N, R12W, SE, Sec. 28, Arizona Upland, 1 May 1979, BLM 2409 Extends records at Fort Mohave, Arizona by Fowlie (1965) 75 km to SE and 150 km to the west of that reported by Hahn and May (1972).

Phyllorhynchus decurtatus—Mohave County, Arizona, ca 2,020 ft. Big Sandy River, 4.6 km N Wikieup, on Hwy 93 T16N, R13W, SW, Sec. 10, Mesquite Bosque 7 July 1977, KBJ 3800 Extends range 35 km NW (Hahn and May, 1972). Not collected.

Chilomeniscus cinctus—Maricopa County, Arizona, ca 2,200 ft. 20 km ENE Wickenburg, T6N, R2W, NE, Sec. 9, Mesquite-dry wash, 20 June 1979, BLM 1288 A common resident of sand bottom washes even at the margins of its distribution. Over 25 individuals recorded in 12 different locations. Extends record by Hahn and May (1972) 70 km to the west of Fort McDowell.

Lichanura trivirgata—Mohave County, Arizona, ca 4,200 ft. Cerbat Mountains, 15 km NNW Kingman, T22N, R17W, SW, Sec. 13, Mohave Desertshrub in the vicinity of a mine, 8 August 1977, BLM 5002. Extends record by Hahn and May (1972) by 125 km to the NW. One additional record at the Boriana Mine Hualapai Mountains, T18N, R16W, NW, Sec. 35, ca 3,900, Mohave desertshrub, 19 April 1979.

Masticophis bilineatus—Mohave County, Arizona, ca 4,800 ft. Hualapai Mountains, 24 km ESE Kingman, T20N, R14W, NW, Sec. 18, Interior Chaparral-Pinyon-Juniper Integrade, 5 May 1979, BLM 2411 Extends distribution 80 km to the northwest (Medica and Maza, 1974).

Masticophis taeniatus—Mohave County, Arizona, ca 4,860 ft. Hualapai Mountains, 25 km ESE Kingman, T20N, R14W, SW, Sec. 19, Interior Chaparral-Pinyon-Juniper integrade, 7 June 1979, BLM 2412 Extends distribution by Stebbins (1966) 75 km to the west.

Thamnophis cyrtopsis—Mohave County, Arizona, ca 4,700 ft. Hualapai Mountains, 40 km SSE Kingman, T19N, R16W, NW, Sec. 33, Old Camp Well, Interior Chaparral, 11 August 1977, BLM 2413 Extends range (Stebbins, 1966) 150 km to the WNW.

Crotalus viridis cerberus—Mohave County, Arizona, ca 5,240 ft. Hualapai Mountains—Blue Tank Wash, 40 km NW Wikieup, T19N, R15W, SW, Sec. 33, Interior Chaparral, 24 May 1979, BLM 2414 Extends the range established by Fowlie (1965) 60 km to the SW. Not collected. Photos of this specimen available.

CENTER FOR BIOSYSTEMATICS RESOURCES

Biological Information Services

Do You Have A Need For:

- The names of biologists who will provide information or taxonomic services for a given group of plants or animals in a particular geographic region.
- The names of museum collections which contain biological specimens from particular geographic regions, names of museum curators, and the services provided by the museum.
- The accurate and up-to-date lists of federally endangered and/or threatened species of plants and animals.
- Lists of endangered, threatened, and otherwise regulated species which are controlled by the fifty States and the Virgin Islands.
- Information on obtaining permits for the importation, collection, transportation, etc. of federally and internationally regulated plant and animal species.
- The development and maintenance of a computerized list designed specifically for you.
- Someone to manage an interdisciplinary project for which you do not have the time, facilities, or trained personnel.

The Association of Systematics Collections, through its **Center for Biosystematics Resources,** provides these and many other services to biologists, state and federal agencies, industry, and other interested organizations and persons.

Fees for Services: * (SSAR members may receive 10% **discount.** See **HR** 12(4):114)

Typical Fees **

—Permitting Information	$ 12.00 to $ 24.00
—Controlled Species Information	$ 12.00 to $ 18.00
—Computer Searches	$ 15.00 to $400.00

* Services offered by the **Center** are free of charge to those individuals associated with ASC member institutions. Fees effective **1 October 1980.**

** Actual fee based on computer usage and staff time.

For more information on the Center and how it might be of use to you, contact the ASC at 913/864-4867 (FTS 752-2314) or fill out the form below and mail it to — Association of Systematics Collections, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045.

CENTER FOR BIOSYSTEMATICS RESOURCES

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles is pleased to announce that proposals are now being accepted for the 1981 Grants-In-Herpetology Program. This program is designed to provide financial support to deserving individuals or organizations engaged in research on or conservation of amphibians and reptiles. Grant proposals will be considered in the following areas:

1) **HERPETOLOGY-ORIENTED CONSERVATION.** Proposals should address research on endangered or threatened species at the state, national or international levels, or address research on critical herpetological habitats. Proposals may be received from individuals only.

2) **GRADUATE STUDENT HERPETOLOGICAL RESEARCH.** Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only, with a letter of support from the student's major advisor or committee chairperson.

3) **REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS.** Proposals may address any herpetological research endeavor or project, provided said endeavor or project concerns herpetology within the implied geographic limits of the regional society. Proposals may be submitted by regional herpetological societies or by individuals. If the latter, a sponsoring letter from the current societal president or an advisor should accompany the proposal.

4) **HERPETOLOGICAL RESEARCH IN ZOOS.** Proposals may address any herpetological research endeavor which is conducted at a zoo. A letter from the represented zoo or supporting institution should accompany the proposal.

Each proposal should include the following information: A) **Background & Objectives** of the proposed project, in terms of its relevance to herpetology, B) **Methods** of carrying out the research or conducting the project, C) **Budget** for the project, according to the guidelines set forth below, and D) **Letter of Support** (if applicable). Proposals should be relatively brief (approx. 5 typed pages).

Budgets for the proposals should not exceed **$250** in each category. The budget request should specifically relate to the project under consideration.

Successful applicants will be expected to submit to SSAR a written report of the results of their research or project, within a reasonable time after the project year is completed. They are also encouraged to submit for publication the results of their research or project, preferably to **The Journal of Herpetology** or **Herpetological Review.**

Members of the SSAR Grants-In-Herpetology Committee will evaluate all proposals, projects or programs. Committee members are: Martin J. Rosenberg (Chairperson), Douglas Fraser (Regional Herpetological Societies), Terry Graham (Conservation), John Groves (Zoo Research) and Ralph W. Axtell (Graduate Student Research).

Individuals submitting proposals should designate to which of the four areas their proposal applies. All proposals must be typewritten and submitted in duplicate no later than **15 APRIL 1981** to:

Martin J. Rosenberg
Department of Biology
Case Western Reserve University
Cleveland, Ohio 44106

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Houston Zoological Gardens, Houston, Texas 77001.

FIRST SUCCESSFUL CAPTIVE PROPAGATION OF SCHNEIDER'S SMOOTH-FRONTED CAIMAN, *PALEOSUCHUS TRIGONATUS*

INTRODUCTION

Of all the crocodilians, the genus *Paleosuchus* is perhaps the least known. Neither of the two species assigned to the genus, *P. palpebrosus* (Cuvier, 1807) and *P. trigonatus* (Schneider, 1801) is well known. Specimens of the genus are found in South America, in swift moving, often turbulent waters of the tropical rain forest. The southernmost locality appears to be Bahia; to the west it is found from Rio Abuna, Bolivia, and from the Huallaga and Ucayali in Peru. In the north, it is known from the Rios Sansa and Ocoa, Colombia, and as far north as Angostura on the Rio Orinoco, Venezuela. To the east, it is found mainly in Guiana, Surinam and Mexiana Island. Both species apparently occur together not only over most of the Amazon and Orinoco basins, but even as far as extreme eastern Brazil (Medem, 1958).

Although their hide, because of its osteoderm, is of little value, they are hunted by natives for use as food and such activity very likely has reduced their range since the above distribution was recorded. Medem (1958) noted that individuals, even juveniles, were always solitary. It is known that they hide most of the day and hunt in late evening (Medem, 1958). There are a few *Paleosuchus* in captivity. In a survey of American zoos only 15 animals were located: 5 males, 3 females and 7 of undetermined sex (King and Dobbs, 1975). Information on reproduction in the genus is incomplete. Only recently has work been done on *P. palpebrosus* (Medem, 1972), resulting in successful propagation, and only preliminary reproductive data from eggs found in the wild are available for *P. trigonatus* (Dixon and Soini, 1975). Here I report the first successful captive propagation of *Paleosuchus trigonatus.*

MATERIALS AND METHODS

The Zoological Society of Cincinnati obtained a juvenile male *P. trigonatus* in March, 1966, and a juvenile female in May, 1967. Both were purchased from the same individual but no locality data are available. Eventually they were placed in a circular pool, with a concrete island, located in the Reptile House lobby. The pool housed many other species of crocodilians of varying ages and sizes. Breeding

was first observed early in 1975. Eggs were laid on the night of 24 March, 1975, on the island. Unfortunately they rolled into the water and all were broken but one, which proved to be infertile. It was then decided to concentrate efforts with these *Paleosuchus* and isolate them in a separate enclosure, which was provided in September, 1975.

The new enclosure is a large indoor exhibit located at one end of the Bird House. The area is densely vegetated with live plants and covered with a large skylight which provides a natural photo-period. The enclosure consists of a pool 3.35 X 3.66 X 1.22 m in depth, rising at a gradual incline to a land area of 3.66 X 2.44 m. The water temperature ranged from 21°C in winter to over 27°C in summer. The air temperature was about 21°C in winter, with the summer temperature determined largely by the outside natural conditions. The area was readily open to the public, with only a railing fence as separation. Prior to isolation in the new enclosure, the female specimen was 1.22 m in length and the male specimen was quite large at just over 1.83 m. Their diet consisted of blue fish, horse meat, and rats as supplements. They were fed twice a week in summer and offered feed every 10 days in winter, but the animals showed little interest in feeding during the winter. The move to the new enclosure proved to be quite traumatic for the two caiman and resulted in both animals going off feed for nearly one year. No signs of breeding were noted, but early in 1979 eggs were produced. These eggs were removed and incubated artificially. They were placed in a styrofoam container (180 mm deep and 415 mm square) and covered with peat moss. The eggs were buried in the center, and the container was covered with a sheet of glass. Incubation temperature fluctuated from 29°C-31°C and from 92-100% relative humidity. Periodically the peat moss was sprayed with water. Temperature and humidity of the peat moss were monitored twice daily (early morning and late afternoon) and a visual check of the eggs was made weekly. The artifical incubation resulted in the hatching of six caiman.

RESULTS AND DISCUSSION

Seventeen eggs were observed on 8 January, 1979, at 0200. The eggs had apparently rolled into the water, but could not be retrieved until 0700. Water temperature upon removal was 15°C. When removed, the eggs were covered with a clear gelatinous substance. Because it was unknown if the five hours in water had ruined the eggs, one egg was opened after 28 days. It was found to be fertile and there was visible body development (eyes and beginnings of leg protrusions and a visible heart beat).

Since the incubation period for *P. palpebrosus* is known to be 90-92 days (Medem, 1972), the eggs were candled on 4 April, after 94 days of incubation, and of the 16 eggs remaining, 7 were found to be fertile. All eggs were uniform in size and weight with a rough calciferous surface (Fig. 1). With no signs of hatching after 102 days, another egg was opened on 10 April. This particular egg was

Figure 2. Young caiman after entering water. Fred Straub, Cincinnati Enquirer.

noted by Medem (1972) for *P. palpebrosus*. Since Medem (1972) found that a hatchling *P. palpebrosus* placed directly into water died, the young caiman was placed in a tank containing a mixture of moistened sheet moss and peat moss and a piece of cork bark under which it could hide. The caiman was kept in this container for 24 hours, in keeping with the notion that hatchlings in the wild spend from 24-48 hours in debris and dry leaves to allow the mucus to dry completely and to allow a toughening of the hide to occur. This procedure was repeated with the remaining hatchlings.

By 7 May, 118 days after the eggs were laid, six caiman had hatched (Table 1). Three responded to the call and egg movement procedure and immediately emerged; one came out at night on its own, and two cracked their eggs and returned a call but remained in the egg up to 48 hours before completely emerging. After the 24-hour drying-out period, the young were placed in a 30-gallon aquarium with one end elevated about three inches. The higher end contained moistened peat and sheet moss mixture; the lower end contained water and a cork bark shelter. All hatchlings remained on the elevated moss area, often digging under moss for seclusion, and then entered the water during the dark evening hours. They continued their seclusion under the bark and seldom left the water (Fig. 2).

calling procedure was repeated, in a single motion, the young caiman propelled itself headfirst out of the egg. The hatchling was covered with a thin clear mucus, like that selected because it had a small crack in one end of the shell, with a clear substance containing blood vessels protruding. The egg contained a live, alert animal thought to be 1-3 weeks premature. The animal measured 180 mm and was fully developed except for a small amount of scale area around the yolk sack attachment area. The young caiman, still in the lower half of the egg, was placed in a small covered container with moist paper towel to retard moisture loss. It lived for 25 hours, during which time it remained alert and defensive but made no effort to free itself from the egg sack. The animal was preserved (CVG - A. 38089).

Although incubation had gone well beyond the expected time, it was decided to let the remaining eggs run their full course. Beginning 1 May, 112 days after oviposition, the eggs were uncovered daily and a grunt call was made along with a gentle movement of the eggs to simulate the actions of the adult female caiman (Medem, 1972). The peat moss covering was sprayed with water each time to replace any moisture loss and maintain the desired humidity level. On 3 May, after 114 days of incubation, as the eggs were moved, a crack developed in one. Because the crack neither extended nor widened and no return call came from the egg, it was covered again and left for the night. The next morning (14 hours later) the cracked egg looked the same. However, after the movement of the egg and

TABLE 1. Weight and Length Measurement for Six Hatchling *Paleosuchus trigonatus*, on 9 May, 1979

	Length (mm)		Weight (g)
	Snout-Vent	Tail	
1.	112.0	110.0	45.5
2.	111.0	110.0	46.2
3.	111.0	96.0	46.5
4.	110.0	112.0	43.5
5.	110.0	110.0	44.0
6.	109.0	112.0	47.5

The adult female caiman is known to aid in the cracking of the shell if the hatchlings cannot get out on their own (Medem, 1971). In the present case, the hatchlings readily cracked the eggs themselves. Actually, at the point of hatching, the hard, brittle outer shell seemed to be visibly weakened with the hairline cracks and fell away easily from the thick inner membrane as the young emerged. Of the six hatchlings, one developed an abdominal problem and died two weeks after birth. The animal was preserved (CVG - A. 38131). The remaining five were alert and healthy in appearance and were offered a first food of crickets (dusted with vitamins) after 14 days. When these were readily accepted, live gold fish and live juvenile mice were added to the diet and kept available to the caiman at all times. As of 19 October, 1979, all five are doing well and growing rapidly.

ACKNOWLEDGMENTS

I would like to thank Edward Maruska, Kraig Adler, Leslie Garrick, and Richard Davis for reviewing this manuscript, and those others who gave helpful comments. The two dead embryos (CVG - A.38089, CVG - A. 38131) are in the Cincinnati Zoo's preserved collection.

REPRODUCTION OF THE BALL PYTHON, *PYTHON REGIUS* IN CAPTIVITY

Nothing is known concerning the reproduction of the Ball python *(Python regius)* in the wild and information on breeding this species in captivity is scant. Logan (1973) reported successful hatching of several clutches of ball python eggs incubated artificially at about 80°F (27°C). We are not aware, however, of any published accounts of hatchings from eggs that were tended to by the parent. There is a single, curious report of a ball python that was said to have given birth to 11 young (Anonymous, 1941).

Recently we had the opportunity to observe two instances of reproduction of *P. regius* in captivity in which both females were allowed to remain with the eggs.

MATERIALS AND METHODS

The first pair of ball pythons was quite small: nine days before the eggs were laid on 10 June, 1978, the female (VM76-02RG) weighed 980 g, the male was 911 g. The second pair was much larger, 11 days before oviposition the female (EB77-04RG) weighed 2,010 g, the male was 1,615 g.

On 10 June 1978, female VM76-02RG was transferred to a 60 X 30 X 30 cm aquarium tank, the bottom of which was covered by a 2 cm layer of packed down, damp peat moss. This in turn was covered with a 3 cm layer of damp sphagnum moss. An angulated slab of weathered driftwood was placed in one side of the tank to serve as a hiding place and nesting site. Two incandescent light fixtures were mounted on the pegboard cover at the opposite end of the tank. The light bulbs were used to regulate temperatures within the tank. One of the bulbs was red and was left on almost continuously. The other, a white bulb, was turned on only during the day. Relative humidity was kept at over 90 percent at all times by periodic misting.

Temperatures among the eggs within the body coil of the female, within the nesting site of the substratum and of the air within the tank, were measured with appropriate thermistor probes and a 12-channel YSI Model 44-TD Thermistemp Telethermometer as described previously (Van Mierop and Barnard, 1976). A piece of dark cloth was suspended from the tank cover to shade the air thermistor probe from the light bulbs. The aquarium was placed on a layer of insulating material.

Female EB77-04RG was placed in an aquarium measuring 90 X 38 X 30 cm on 15 March, 1979. Interior arrangements were similar to those described above.

OBSERVATIONS

Data on Female VM76-02RG prior to 10 June, 1978 are fragmentary. Room temperature was about 24°C. An incandescent light bulb mounted in the cage was usually but not always turned on during the day. No matings were observed. The female refused to feed after March 1978 and there was a gradual change in temperament. The ordinarily timid and inoffensive animal became irritable, struck at being disturbed, actually biting on several occasions. There was an increasing tendency to bask under the lights and to turn the mid and rear portions of the body sideways or upside-down while basking. This behavior continued after transfer to the aquarium tank.

Late in the morning of 19 June, 1978, four white eggs were laid. Three of these adhered to each other, the fourth was separate. Two of the eggs could be measured (Table 1), the other two appeared to be of about the same size. After egg laying was completed the female coiled tightly around the eggs. Ambient temperature at oviposition was 29.5°C. During the first 18 days of brooding, the ambient temperature was allowed to fluctuate between a mean low in early morning of 27.6°C (lowest 26.2°C) and a mean high in late afternoon of 32.5°C (highest 33.2°C). Corresponding mean nesting site and coil temperatures were respectively: low 28.1°C and 28.5°C, high 32.1°C and 31.6°C. Lowest measured temperatures at these sites were 27.0°C and 28.0°C, highest temperatures were 32.7°C and 32.3°C. The body temperature of the female therefore followed the fluctuations of the ambient temperature rather closely (Fig. 1). From day 19 on, the morning temperature was kept somewhat higher. The red light was turned on at night, and at times during the day, the white

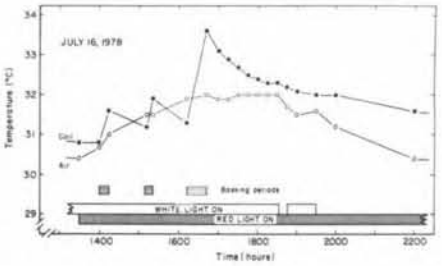

Figure 1: Ambient and coil temperatures measured over a four day period during brooding of a female ball python, *Python regius*.

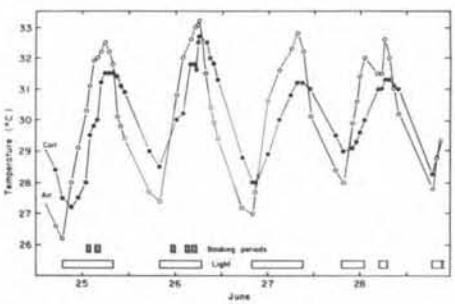

Figure 2: Effect of basking on coil temperature of a brooding female ball python.

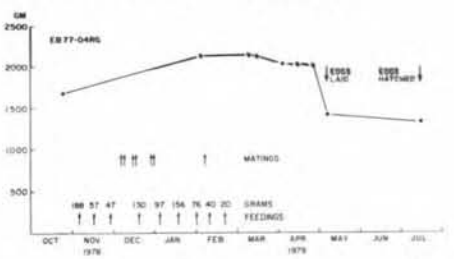

Figure 3: Weight of female ball python before and during gravid period, after oviposition (estimated) and after eggs had hatched.

one only during the day. This arrangement resulted in a mean morning low ambient and coil temperature of 30.2°C (lowest 29.2°C), mean late afternoon high temperatures of the air and the coil were 32.4°C and 31.6°C (highest 34 and 33°C). Mean coil temperature for the entire incubation period was 30.6°C.

The female left the eggs nearly every day for short periods, usually in early afternoon and sometimes more than once, to bask under the incandescent lights. Longest observed basking period was about 50 minutes. When disturbed the animal would immediately return to the eggs. After such a basking period the coil temperature increased by as much as 2°C, but under the existing nesting conditions it would return to slightly above ambient within a few hours (Fig. 2).

The female continued to be very protective of her eggs and struck at the glass when disturbed. A small freshly killed rat was refused on 21 June, three others offered on 3, 14 and 23 July were readily taken. The female shed outside the nesting site on 13 July. No excreta of any type were produced during the entire incubation period. About one week after oviposition, two of the eggs began to collapse and subsequently the shells turned yellowish-brown. Since there was no evidence of putre-

faction these eggs were not removed.

The two remaining eggs began to hatch on 21 August after an incubation period (between oviposition and the appearance of slits in the eggs) of 63 days. Both young had left the shell two days later and exhibited typical ball python behavior. One shed 11 days after hatching, the other two days later. Live, newborn rats were taken after the first shed and by one year of age on a diet of rats, the young had increased their weight six-fold (Table 1).

The two collapsed eggs contained a firm mass which resembled hard boiled egg white. There was no evidence of decay nor was there any trace of an embryo in either egg. Several earwigs *(Forficula auricularia)* had tunneled into the interior of the eggs and had deposited their own eggs. In addition there were numerous tiny olichaetes and entomobryid springtails. pH of the substratum was about 6 as tested with a reagent strip.

The second pair mated several times between 5-30 December, 1978. The male was removed 3 January, 1979, and reintroduced to the female a month later. Two further matings were observed on 6 and 7 February. Ambient temperature at these times varied between 23° C in the morning and 28-30° C in the afternoon. The animals were permanently separated on 10 February. The female accepted her last meal, a small mouse, on 20 February.

Body weight of the female increased from 1675 g on 24 October, 1978, to 2131 g on 4 February, 1979. Thereafter there was a slight weight loss to 2010 g on 26 April (Fig. 3). Temperature within the nesting site after transfer to the aquarium tank of 15 March fluctuated between 26-27° C in the morning to 29-30° C in the afternoon. The behavior of this female (irritability, basking, unusual body positions) was as described for female VM76-02RG. On 15 March, a marked enlargement of the midbody was noted which persisted for about a day. At the same time the distal one-third of the body had become more slender than before, *i.e.* the previously diffuse enlargement of the entire rear portion of the animal had shifted proximally and had become more localized. After about 24 hours the bulge disappeared and the rear part of the body resumed its "full" appearance as before.

Between 0800 and 1100 hr on 7 May, 1979, seven eggs were laid. One of these fell outside the coil and was removed. It was weighed and measured (Table 1) and after candling, which demonstrated a vascular system already in an advanced state of development, put in a glass container on a substratum of damp peat and sphagnum moss. The container in turn was placed in the aquarium tank in an area where the temperature was similar to that measured within the coil of the female. Behavior of the female during brooding was as described above except that she refused to feed throughout the incubation period. Temperature within the coil (lowest 28.5° C, highest 32.5° C) varied with that within the nesting site (lowest 28° C, highest 33° C). Mean coil temperature over the entire incubation period was 30.1° C, slightly lower than in the case of VM76-02RG. Humidity again was kept very high.

On 9 July the eggs no longer adhered to each other and the female was unable to coil around the scattered eggs. All were removed, candled, weighed, measured and placed in an incubator at 30.5° C. All were fertile and stained deep brown where they had rested on the peat substratum. The pH of the substratum as measured with a Radiometer Model BMS 3 Mk 2 blood gas and acid-base analyzer was 4.9. No organisms were seen.

On 13 July, the eggs, including the one incubated separately, began to hatch and three days later all young had left the shell. The young snakes shed between 28-30 July.

Table 1. Measurements (cm) and weights (g) of females, eggs and young of *Python regius*.

Female #	VM76-02RG	EB77-04RG
Weight of ♀ before oviposition	980	2010
Number of eggs	4	7
Total weight of eggs (est.)	320	595
Weight of ♀ after oviposition (est.)	660	1415
Weight of ♀ after eggs hatched	—	1342
Egg length, after oviposition	6.5	7.8*
Egg width, after oviposition	3.8	4.3*
Egg weight, after oviposition	—	84*
Egg length, before hatching	8.2*	7.2
Egg width, before hatching	4.1*	4.8
Egg weight, before hatching	86*	101
Hatchlings, length	38	43
Hatchlings, weight	56	67
Juveniles, length at one year	75	—
Juveniles, weight at one year	359	—

* Single egg, all other measurements and weights of eggs and young are mean values.

DISCUSSION

Some features of the reproductive cycle of *P. regius* are similar to those of *P. molurus*, the python species which has been studied most often and in the greatest detail. As in *P. molurus* and most, if not all other pythonid snakes (Benedict, 1932; Lederer, 1944, 1956; Ross, 1973; Ross and Larman, 1977; Sclater, 1862; Stemmler-Morath, 1956; Valenciennes, 1841; Van Mierop and Barnard, 1976, 1978; Walsh, 1977), the female ball python stops feeding some weeks after mating and coils around the eggs until they hatch. Unlike *P. molurus*, however, the ball python female will leave the eggs for brief periods to bask or, at least in some cases, to feed.

The statement has been made repeatedly, as for example by Logan (1973) for *P. regius*, that female pythonid snakes gain weight when gravid. Since no food is taken such a weight gain could only be explained on the basis of fluid retention. Female EB77-04RG was weighed several times when gravid. This showed that the animal actually lost weight (Fig. 3). Our observations with gravid *P. molurus* also have demonstrated that the "weight gain" is an illusion created by the fact that the rear portion of the body becomes larger while at the same time the anterior part of the animal becomes thinner. In other words, there is a redistribution of body mass, rather than a true weight gain.

The peculiar and pronounced local enlargement at midbody which lasts for about 24-36 hours and which occurs some 50 days prior to oviposition, we have also seen in *P. molurus*. The explanation for this phenomenon could be that ovulation occurs at that time and that the eggs migrate anteriorly, crowding together, in order to enter the oviducts.

We have found no evidence that the ball python becomes temporarily endothermic. Pitman (1973) stated that the "brooding female African *Python regius* able physiologically thermoregulate body temperature maintain heat above eggs lower critical temperature (33° C) and some 5 degrees higher than ambient temperature, to aid incubation", and "no evidence available — ability *P. sebae* thermoregulate body heat by conspicuous musculature contraction as do *P. regius* and Asian *P. molurus*". Pitman does not elaborate or give his source. According to Logan (1973), *P. regius* twitches when incubating. We have not found any evidence that the female ball python is able to regulate body temperature and produce heat endogenously by means of contractions of the body as has thus far been proven only for *P. molurus* (Hutchison, Dowling and Vinegar, 1966; Vinegar, Hutchison and Dowling, 1970; Van Mierop and Barnard, 1976, 1978). The behavior of the female as observed in this study however does suggest that this species, if given the opportunity to do so, may be able to maintain a more or less constant incubation temperature by behavioral means, i.e. by selection of nesting site and by basking, as has been observed by Cogger and Holmes (1960) for the carpet python *(Morelia spilotes variegata)*.

The relatively very large size of the eggs of *P. regius* has been commented upon previously (Logan, 1973; Pitman, 1973). Unlike the eggs of *P. molurus* which lose weight during incubation, those of the ball python increase in size and weight as do the eggs of most other snakes.

The incubation periods of 63 and 67 days were considerably shorter than the 97 to 102

days reported by Logan (1973). This difference undoubtedly is related to the higher mean incubation temperatures of 30.6 and 30.1° C as compared to about 27° C in Logan's study.

BOOK REVIEWS

Wever, E. G. 1978. **The Reptile Ear. Its Structure and Function.** Princeton Univ. Press. xii + 1024 pp. ill. ISBN 0-691-08196-4. $50.

This book reminds me in so many ways of Gordon Walls' *The Vertebrate Eye:* it is comprehensive; it is profusely illustrated; it is lucidly written; it has universal appeal; and it is bound to become a classic.

The text is divided into four parts. The Introduction describes the techniques used for studying the ear, an organ so constructed that extraordinary methods of dissection, fixation and sectioning are required. Prior to dissection, sensitivity was measured on the intact ear of the anesthetized animal as the sound pressure required to produce a standard cochlear potential of 0.1 μv. When these pressures are determined over a spectrum of sound frequencies, the plot is U-shaped and the bottom of this curve represents those frequencies to which that particular ear is most sensitive. Anyone who has worked with reptiles knows how frustratingly incomprehensible their reaction to sound stimuli can be. The above technique overcomes this problem and enables comparison of auditory capabilities among different species. The General Anatomy of the Reptilian Ear and Sound Transmission to the Cochlea and the Stimulation Process conclude the introductory part.

Part II, by far the longest, describes the ear in the various families of lizards; part III includes snakes, amphisbaenians, *Sphenodon*, turtles and crocodiles. Each segment is introduced with a list of the toal number of specimens dissected, measured and described for each species that the author was able to obtain. I was tempted to count the number of reptile families, species and specimens represented in this opus, but after the first listing (Iguanidae) of 47 species, 149 specimens, I decided simply to state that the numbers are impressive and that they obviously represent a lifetime of meticulous, devoted, labor. The anatomy of the outer (when present), middle, and inner ear is described in detail for each species, anomalous or unusual details are pointed out, the sensitivity curve is provided and whenever known, (unfortunately, not too often) the relationship between the ear structure and the ecology of the species.

Part IV is a brief concluding summation of the writer's interpretation of the probable evolutionary history of the ear: the vertebrate cochlea emerged independently out of the non-auditory labyrinth in three different vertebrate groups: fishes, amphibians and reptiles, while the ear of birds and mammals followed the pattern of the reptilian ear. However, among the reptiles, especially the lizards, diversification has occurred in a number of ways, especially in the means of restraint of the ciliary tufts of the hair cells.

No reptile is deaf. Even those without external ears can perceive aerial vibrations, most quite well. Considering that reptiles as a group are not renowned for their vocalizations, the role that the ear plays in their survival is still mostly conjectural; that indeed it must have an important function is convincingly documented in this fascinating monograph. A copy of this book belongs in the library of every herpetologist.

Ohio University
Athens, Ohio 45701

Herpetological Explorations of the Great American West. Edited with an introduction by Kraig Adler. 1978. Arno Press, New York. A two volume facsimile reprint of 24 studies by fifteen authors. Pagination indeterminate (*ca.* 2¼ inches thick—both volumes). $75.00.

This two-volume facsimile publication of collected rare works on the herpetology of the western United States (and Mexico) is a valuable compilation for anyone interested in North American amphibians and reptiles. The geographical area treated in these two volumes spans from Arkansas to the Pacific coast, and from the Canadian border into Mexico. As in other volumes of this series by Arno Press, the lack of overall consecutive pagination causes difficulty in locating a specific paper—one must search for a title page to locate the desired work. Otherwise, the two volumes are tastefully bound, well-organized and easy to read.

Included in this collection are herpetological portions of seven works by Baird, Cooper and Hallowell devoted to explorations for a railroad route from the Mississippi River to the Pacific Ocean. I feel their inclusion is of tremendous value since they had previously created (for me) a bibliographic nightmare. The seven papers are fully referenced and organized, and should eliminate much of the confusion regarding these surveys and their dates of publication. Also included (in volume

two) is the complete 1865 work of Maximilian, Prinz zu Wied, on his explorations in North America. This study alone commands prices of over $100.00 from book dealers, and, when this is considered, the price of $75.00 for these two volumes seems quite reasonable. I consider these collected works a good buy and a useful addition to any herpetological library.

A Guide to Field Identification: Amphibians of North America. By Hobart M. Smith. Illus. by Sy Barlow. 1978. Golden Press, New York. 160 pp. $4.95.

This book, written by one of America's most distinguished herpetologists, is not only a useful field guide to the salamanders and anurans of the United States and Canada, but is also a compact handbook of North American amphibians, of value to both amateurs and professionals.

Amphibians of North America begins with a general introduction to the amphibia, including sections on habits and habitats, collecting techniques, and an important paragraph on "Ethics for the Enthusiast." A chapter on the physical characteristics of the families of American amphibians follows, accompanied by generalized drawings indicating the important characters used in species identification.

Of special interest to amateur readers are chapters explaining basic taxonomy and the use of identification keys. The author also describes the "policies of the book," including his decision to de-emphasize the naming and description of subspecies. This is a significant deviation from other popular field guides on amphibians.

The "identification" section for each order of amphibian is preceded by a general discussion of the structure and life history of the animals. All points are clearly illustrated and labeled, allowing readers untrained in amphibian biology and physiology to comprehend the text. For example, the section on frogs and toads includes descriptions and illustrations of the "topography of an anuran," "typical anural life history," "kinds of vocal sacs," and "distinguishing the sexes." A key to tadpoles is offered, allowing identification to the genus level.

Illustrated keys are an integral part of the identification system used in this book. To be useful and accurate, keys must often refer to characters which are difficult for the untrained amateur to visualize and understand. Smith and Barlowe have at least partially overcome this problem with the use of diagrams numbered to correspond with statements in the keys.

Identification of a specimen could be accomplished by going through a series of keys. Thus, the description of each order includes a key to the families; where necessary this leads to a key to the genera, and the introductions to the larger genera include keys to the species. The author, however, realizes that most users of this book will first rely on the illustrations of the species to identify a specimen, thus the recommendation that the keys be used to "verify" a proposed identification.

The descriptions and illustrations of species are arranged as in other field guides in the Golden series, *i.e.* with the range map and text for a species on the left-hand page, and its illustration(s) on the facing page. This system is certainly more convenient than one which requires the user to flip through a book to check illustrations, text, and range map for a species, but it is not without its costs. It limits the space available for descriptive text—and may partially explain the need for de-emphasizing the descriptions of subspecies in this guide, which are often terse. Greater reliance must then be placed on range maps for determination of subspecies, which leads to one of the few problems in using this book. The maps are very small and do not show state or provincial boundaries. Ranges of subspecies are "color-coded" to the text description; some difficulty in interpreting the maps may be encountered, particularly for forms with very limited ranges. A reader who is color-blind might also have some problem with the color-code system.

In general, the species descriptions are adequate, and Barlowe's illustrations are accurate and skillful. All species are shown in color, with color variations included where necessary. Diagrams are used to show morphological details useful in identification.

Following the species descriptions, Smith has included interesting and well-written chapters on "amphibian evolution, distribution, and anatomy," "reproduction" (including growth and longevity), "behavior" (amphibians do not hibernate, it seems—they instead "brumate"!), "enemies and self-defense" (including a rather depressing section on "Ecological Status" where Smith notes that "total eradication of amphibians is not likely, but their diversity will be greatly diminished. There appears to be no practical means of preventing this outcome.").

There is no bibliography, but the section entitled "Other Sources of Information" lists addresses for selected museums having important herpetological divisions, and mentions a number of good, generalized texts and literature references dealing with amphibian identification and biology. There is also a useful cross-referenced index.

Many of the common and scientific names used in *Amphibians of North America* differ from "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (Collins, *et al.*, 1978), published by the Society for the Study of Amphibians and Reptiles in 1978. Smith was a co-author of that report. As mentioned previously, no common names were assigned to subspecies in this new field guide, and a few species names have been changed. Smith has "arbitrarily" restricted the name "frog" to the advanced anurans (true frogs and treefrogs), while all other anurans are considered "toads." It will be interesting to see if the herpetological community will accept this usage; there will almost certainly be some resistance to a few of the common names chosen by Smith. For example, he uses the name "Peeper Treefrog" for the species *Hyla crucifer*, rather than the established name "Spring Peeper." *Ambystoma talpoideum* is called the "Talpid Salamander" instead of the more familiar name "Mole Salamander" (perhaps to avoid confusion with the common name for the family to which this species belongs?).

The scientific names in this field guide are as current as possible, but in a few cases Smith has chosen to differ from Collins, *et al.* (1978). For example, the genus name *Spea* is adopted for several of the western Spadefoot Toads *(S. hammondi, S. intermontana, S. bombifrons); Spea* has been considered a subgenus of *Scaphiopus* by previous workers, and Collins, *et al.* (1978) retained *Scaphiopus* for all of the North American Pelobatids.

Smith has figured range maps for the problematical species *Hyla versicolor* and *Hyla chrysoscelis,* though the map for the latter species is described as "largely conjectural." The ranges depicted for these two species are mutually exclusive, although recent work has shown that *H. versicolor* and *H. chrysoscelis* may occur sympatrically in some areas (*i.e.* Jaslow and Vogt, 1977, and Johnson, 1977). In the present book, the latter species' name is spelled *"chrysocelis"*, in apparent error.

A Guide to Field Identification: the Amphibians of North America will inevitably be compared to the amphibian sections of previous American field guides, such as Stebbins (1966) and Conant (1975). This reviewer feels that the Smith/Barlowe guide should be considered a valuable companion volume to these previous works, and not a competitor. Smith and Barlowe have made a fine contribution to popular American herpetology with this new field guide, and it definitely deserves a place in the library of all persons interested in the amphibia of North America.

TURTLES IN KANSAS

by

Janalee P. Caldwell and Joseph T. Collins

This book presents complete and concise information on the fourteen kinds of turtles currently known to occur in Kansas. Each of these turtles is treated in an account which contains one or more color photographs, common and scientific name, and descriptions of its size and identifying characteristics, habitat, breeding habits, food preferences, predators, defense mechanisms, general range, species with which it might be confused, how to observe it in the wild, and a **detailed** map of its distribution in Kansas.

In addition, this book contains a non-technical key for identifying living turtles, and an illustrated technical key to preserved specimens of turtles for use by biology classes.

Approximately 80 pages
13 figures; 16 color photographs
and 14 maps.

NEWSNOTES

CORRECTION

The following are addenda to the last Legislative Alert column (**HR** 11(4):105):
Hyla andersonii is listed as Endangered *only* in Florida, not throughout its range as implied.
Gopherus agassizii is listed as Threatened *only* on the Beaver Dam Slope in Washington County, Utah, not throughout its range.
Chelonia mydas is listed as Endangered in Florida and the Pacific coast populations of Mexico and Threatened everywhere else (such as in Hawaii and the Trust Territories and Puerto Rico).
Lepidochelys olivacea is listed as Endangered only on the Pacific Coast of Mexico and Threatened everywhere else.
Alligator mississippiensis is listed as Endangered in Oklahoma, North Carolina, Arkansas, Alabama, Mississippi, and inland portions of Texas, Louisiana, Georgia, and South Carolina; Threatened in Florida, central Louisiana, and coastal portions of Texas, Georgia, and South Carolina; and Threatened by Similarity of Appearance in 12 parishes in coastal Louisiana.
Crocodylus porosus is *not* listed as Endangered in Papua New Guinea.

The author and editor regret any confusion caused. ●

HERPETOLOGICAL MONOGRAPH SERIES

The Herpetologists' League has instituted a new publication series — the **Herpetological Monograph Series** — that is intended to serve as an outlet for manuscripts that, owing to their length, are not suitable for publication in traditional scientific periodicals. Contributions should be of broad appeal to the herpetological and scientific communities, and should address topics of amphibian and/or reptilian biology at the organismal level. Although symposia proceedings are not excluded from consideration, preference will be given to monographic works. By establishing the Herpetological Monograph Series, the Herpetologists' League proposes to (1) produce publications of scientific merit and quality, (2) make such publications available at a reasonable cost to the herpetological community, and (3) utilize proceeds from sales of publications to subsidize subsequent monographs.

Persons desiring additional information about this new publication series are invited to address inquiries to the Managing Editor, Linda Trueb, at the Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045, USA. ●

ANTI-HERP AD

30 Crystal Road
Levittown, PA 19057
December 4, 1980

Dear George:

I would like to bring to the attention of the SSAR membership a series of ads by the Nocona Boot Company of Nocona, Texas, that have been appearing in *Playboy* magazine for over a year that I know of. These may also have appeared in additional periodicals, but if so, I have no knowledge of them.

These ads depict the suggested beheading of a western diamondback rattlesnake by a Nocona-shod figure (page 62 of the September, 1979, and again on page 98 of the January, 1981, issues of *Playboy*), and the suggested "removal" of a Gila monster from a Nocona-booted figure with a pair of fence-cutting pliers (page 70 of the December, 1980, issue of same). These same ads may have appeared at other times as well. I don't get the opportunity to thoroughly scan each month's issue of *Playboy*, so can't say for certain. However, I have seen at least one other, similar, ad depicting a scorpion as the victim.

I am especially disturbed by these ads appearing in a periodical with a circulation and impact of the magnitude of *Playboy's*. That magazine wields a great deal of psychological influence, whether intentional or not, and hence, helps to mold many readers' attitudes about a great many subjects. These ads are especially insidious in such an influential source.

Not only is this type of advertising offensive, but it is totally unnecessary as well. In addition, it is counterproductive from the standpoint of the preservation of these animals and in the case of the Gila monster at least, an endangered and protected species is involved.

If other readers are as disgusted by these ads as I am, I urge them to write to each of the following and express their dissatisfaction and to try to bring an end to this ad campaign:

Mr. Enid Justin, President
Nocona Boot Company, Inc.
P.O. Box 599
Nocona, TX 76255
Mr. Dale Gordon, Sales Manager
Nocona Boot Company, Inc.
P.O. Box 599
Nocona, TX 76255
Mr. Russell Weller
Playboy Magazine
Playboy Building
919 North Michigan Avenue
Chicago, IL 60611

Hopefully, with enough SSAR members' support, we can force both *Playboy* and the people at Nocona to realize the destructive nature of these ads and to discontinue them at the earliest possible date.
Thank you very much.

Sincerely,
Joseph R. Dinardo

REPTILE HUSBANDRY SYMPOSIUM

Fifth Annual Reptile Symposium on Captive Propagation and Husbandry to be held Friday thru Sunday, June 12, 13 and 14th, 1981, at the Oklahoma City Zoo, Oklahoma. Papers are still being accepted by Dr. Martin J. Rosenberg, Case Western Reserve University, Biology Department, Cleveland, Ohio 44106. This year's Symposium co-ordinator is Thomas Huff, Director, Reptile Breeding Foundation, P.O. Box 1450, Picton, Ontario, Canada KOK 2TO. Information with regard to accommodations should be addressed to Darell Pickering, Oklahoma City Zoo, 2101 N.E. 50th, Oklahoma City, Oklahoma 73111.

HR REVIEWERS

The editorial staff wishes to thank the following persons for reviewing manuscripts over the past several months:

James P. Bacon, Joseph Bielitzki, R. Bruce Bury, Gary Carl, Charles Carpenter, Archie Carr, Roger Conant, Joseph Collins, William E. Duellman, Stan Dyrkacz, John Ferner, Gary Ferguson, James Gillingham, Gary Harwell, Larry Hunt, John Lynch, C. J. McCoy, James B. Murphy, George Nace, Hugh Quinn.

Their investments of time are much appreciated. ●

POSITION

COLLECTION MANAGER

The Division of Herpetology, Museum of Natural History, University of Kansas, anticipates a position for a full-time collection manager for a period of two years with the possibility of continued funding for a permanent position. The starting date can be from 1 July to 1 September 1981 with a starting annual salary of $18,000 plus fringe benefits. Candidates must have a Bachelor's Degree or Master's Degree in vertebrate zoology, demonstrated knowledge of systematic herpetology, and minimally two years curatorial experience in a herpetological collection in a museum, including supervision of other personnel. Duties will emphasize reorganization and taxonomic updating of collection, preparation of cross catalogues, preparation and curation of osteological and histological materials, and supervision of student employees. **This is not a research position.** Send curriculum vitae and names, addresses and telephone numbers of two references by 1 May 1981 to Dr. William E. Duellman, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045. An Equal Opportunity/Affirmative Action Employer. Applications are sought from all qualified people regardless of race, religion, color, sex, disability, veteran status, national origin, age, or ancestry.

CURRENT LITERATURE TRANSITION

Beginning with this issue, we have a new section editor for Current Literature, Joseph Dinardo. I would like to extend my sincerest thanks to Richard Worthington, past CL section editor, for the outstanding job he did in developing and maintaining this valuable part of *HR*. I doubt if it is possible for me, even as editor, to *fully* appreciate the arduous task of preparing all those citations for publication each issue.

BRACHYLOPHUS MOVIE

The Fiji Film Unit is currently producing a 13 minute film on "*Brachylophus vitiensis*, the Crested Iguana." This unique film contains the first-ever recorded film history of the Crested Iguana and spans a whole year of animal observation, from birth to behaviour in its natural environment on an off-shore island in the Fiji group. The film contains scenes of the animal in its natural environment and in captivity, and includes shots of feeding, (natural), territorial behaviour (natural) and egg hatching (captivity).

The hope is to have the film completed by March/April 1981. The producers can supply a 16mm Eastman colour print or a ¾" U-matic cassette with English commentary at a cost of U.S. $250.00, payable to the Ministry of Information, Suva, Fiji. If you are interested in purchasing a copy of this film please write to the Director of Film Production, Fiji Film Unit, Government Buildings, Suva, Fiji.

Southwestern Herpetologists' Society

The Southwestern Herpetologists' Society is open to anyone having an interest in the study and conservation of reptiles and amphibians.

INTERNATIONAL HERPETOLOGICAL CONGRESS

Oct 3rd - Oct 9th 1981

Organised by the Cotswold Wild Life Park and the Association for the Study of Reptilia and Amphibia. To be held in the large Lecture Theatre, Department of Zoology, University of Oxford.

Provisional Programme

Days 1-2 Captive husbandry and breeding (World Wide); Days 3-4 Conservation and Field Research in Europe; Days 5-6 General Herpetology (World Wide); Day 7 Visit to Cotswold Wild Life Park, Lunch, Discussion and Dispersal.

Offers of papers for the various sections of this congress are now requested. Papers read should be of no more than 30 minutes duration and manuscripts for publication should be limited to 5,000 words and not more than five figures or tables.

Suggested titles should be sent without delay to:
J. Coborn, Cotswold Wild Life Park, Burford, Oxon OX8 4JW, England. ●

CURRENT LITERATURE

As of March, 1978, approximately 87 researchers are scanning 450 journals. Titles are published four times per year. Searchers are encouraged to submit titles for inclusion at three month intervals to assure approximately equal listings in HR.

Anyone publishing in a journal that is not widely distributed is invited to submit a complete citation or send a reprint to insure that the reference is published in Current Literature. Complete citations to obscure references are also welcome. Senior author addresses that are submitted will be included. Addresses following citations are those of first authors unless otherwise noted. Citations should be sent to

Joseph Dinardo

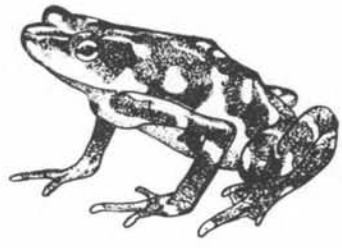
society for the study of amphibians and reptiles

The Society for the Study of Amphibians and Reptiles is a non-profit, international organization established in 1967 to advance the study of amphibians and reptiles. Although begun in 1958 as a regional society, the SSAR rapidly gained a world-wide membership. Today it is recognized as having the most diverse society-sponsored program of professional services and publications for students of herpetology. Membership is open to all persons interested in learning about amphibians and reptiles.

activities



An **annual meeting** is held each summer on a university campus or at a biological station in the United States. The Society especially wishes to attract students to its meetings by providing inexpensive and informal facilities. In addition to the papers given by members at these meetings, a symposium or other invited speakers are usually planned which allow for detailed discussions of an important area of contemporary study. Workshops for regional society representatives have been organized for the purpose of exploring common problems and sharing new ideas. Live animal, photographic, art, and other exhibits are organized, as well as field trips.

The Society makes a concerted effort to involve a diverse segment of its membership in Committee activities designed to further our knowledge of amphibians and reptiles and manage the affairs of the Society. Committees include: Nominating, Student Award, SSAR Grants-in-Herpetology, Common and Scientific Names, Legislative Alert, Regional Society Liaison, Zoo Liaison, Editorial, Translations, and Annual Meeting.

publications

SSAR sponsors one of the most diversified series of publications of any scientific society. Each series is described on the reverse of this page. Back issues of most publications are available; a detailed price-list can be obtained simply by checking the appropriate box on the membership application.

membership privileges

All persons with an interest in amphibians and reptiles are welcome to become members of SSAR. Members vote on society matters, attend meetings, and participate in other Society activities. Each year members receive the following publications: **Journal of Herpetology** (4 issues, totaling about 500 pages), **Facsimile Reprints in Herpetology** (1-2 issues, about 50 pages), **Herpetological Circulars** (1-2 issues, about 50 pages), and **Herpetological Review** (4 issues, about 130 pages).

In addition, SSAR members receive a substantial discount on all book-length **Facsimile Reprints** and **Contributions to Herpetology** issued during the year. Members may also place standing orders for accounts in the SSAR Catalogue of American Amphibians and Reptiles. Those persons electing the higher membership categories (Sustaining and Contributing members) receive the same publications and services, but provide additional financial support which allows the Society to expand and improve its programs more rapidly than would otherwise be possible.

membership/subscription

Please mark those boxes opposite the items you wish to subscribe to or order, fill in your name and address, and return to:
